

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at `http://books.google.com/`

Why a Cone Clutch?

A really good disk clutch is, in a way, better than the cone clutch.

But the construction cost of a disk clutch is four times that of the cone—an amount clear out of proportion to the difference in service.

Disk clutches are not dependable. Even a properly designed clutch of this type may develop inaccuracies of manufacture, warped disks and other failures that go to make the action of a large percentage of this type unsatisfactory and unreliable.

The cone clutch is more accessible and simpler than the disk. Absence from complicated parts always tends toward perfection in the matter of performance.

The strongest argument, however, against the disk clutch lies in the fact that demand for it almost amounting to a craze reduced manufacturing methods to a point where effort was made to produce the disk at the same price as the cone.

The resultant deluge of trouble is causing a logical return to popularity of the earlier form of cone clutch.

The Hartford cone clutch, shown here, made in the largest factory of its kind in the country, is a model of precision as well as of design.

It is a clutch that can be depended upon to work and last—one in which the finest quality of material has been combined with machining refinements—great enough to successfully pass grilling physical tests for strength and accuracy.

The Hartford cone clutch comes in either pressed steel or aluminum. Weight the same, complete equipment 30 pounds. Two sizes 25-30 and 35-45 horsepower.

Let us help you solve your cone clutch problems.
Our engineering department is at your service.

Gentlemen:-

In renewing our contract for motor wagon axles with you for another year, we are very glad to say a good word.

We have had very excellent success with these axles in all kinds of commercial work and in nearly every part of the world. We find that the Sheldon Ball Bearings which you furnish on these axles, stand the usage which our business demands, with splendid success.

With best wishes, we are,

Yours truly,

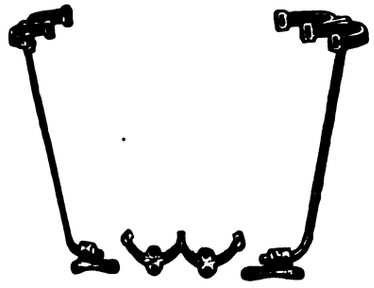
The Mayo—the radiator thoroughbred

¶ Mayo Radiators are standard on a number of well known makes of cars—in all instances, cars in which quality predominates.

¶ Mayo Radiators offer a maximum of radiating service and are immune to leakage except in case of accident. We offer them as models of correct design and construction.

¶ Every radiator is guaranteed to live up to the requirements set for it and we stand back of this guarantee.



¶ Let us give you some facts concerning the Mayo system and its application.

"This is No Place for Us"

You Cannot Use an Old Fashioned Crank On

THE NATIONAL STARTER

Every car equipped with the "hundred and one" self starters, also carries a crank.

You know why.

A self starter that is even 99 per cent efficient is still fallible—and on the first failure, out comes the crank.

The National Starter has no provision made for hand cranking.

The end of the crank shaft is covered by the metal casing shown here.

It's pretty clear, then, that the National Starter must be 100 per cent efficient—therefore infallible.

Archimedes once said:

"Give me a lever long enough and I will move the world."

On this principle we have reduced engine inertia and compression resistance to a minimum.

The National Starter is just an ingenious arrangement of high and low ratio levers hooked up with a segment engaging a bevel gear on the crank shaft—That's all.

You simply push the pedal with your foot, without leaving the car or changing position.

This device operates directly, naturally and mechanically, saving the engine from the terrific shock of exploding gas against the inert piston head—

And it has no operating cost—no bills for gas and upkeep of complicated compressed air or electrical apparatus.

Now, Mr. Dealer, if you want to join the growing ranks of those who see the "handwriting on the wall" concerning the unreliable elemental self starters—

Then write for our proposition.

NATIONAL GAS ENGINE STARTER COMPANY

"The Horn that's Made for the Discriminating"

TUTO HORN

THE TWO TONE HORN

Low Note Horn Necessary

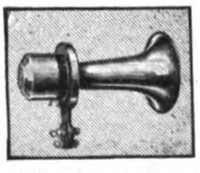
EVERY experienced motorist acknowledges that a low note service warning signal is necessary for ease and comfort in driving.

¶ The laws of most countries demand a low signal note and in many cases the louder signal is barred from use.

¶ The continual use of a one-note-extremely-loud warning signal, rightly invites adverse legislation.

¶ Car occupants, especially women, demand a mild signal for regular service and refuse to put up with the inflexible, unnerving and racking blast of the loud one-note emergency signal.

¶ The loud emergency signal is necessary and many large cities demand it as a part of the motor car equipment.



¶ These same cities surround the use of this loud signal with such restricted regulations, that the driver is in a quandary as to whether the use of the horn will invite arrest, or that the failure to use the signal will promote an accident.

¶ This surely is inefficiency personified.

¶ Why put up with such an inflexible condition when the TUTO Horn, with its double service, will do all of the signalling of the car—a low note for ordinary service, effective 90% of the time—a loud note for emergencies, instantly responsive by a full pressure on the same button that gives the milder signal.

¶ The TUTO Horn comes complete with all materials for installing, so as to make a very neat and most permanent job. The cost is $25.00 in any finish and with a long or short projector.

¶ You will make no mistake to specify the TUTO Horn on your new car.

THE MOTOR WORLD
Hyatt Roller Bearing Editorial

Detroit, Mich., June 27, 1912

Bearing Theory

Advertisements are not read because entertaining fiction can be had in far more attractive dress. How much better it would often be to tell some one interesting fact and let that fact teach its own lesson.

Take for Example the theory on which a roller or ball bearing is constructed. Think for a moment what is asked or expected by so many people of a roller or ball in a bearing—overlooking entirely that each has but a limited capacity, and that either can consistently have but one axis of rotation.

The Most Perfect Bearing of the ball type for radial loads now made is the "two point contact" or annular. In such a bearing a ball 3-8 inch diameter has a maximum safe working load less than 300 pounds. Greater loads produce distortion sufficient to make the ball useless as a transmission element, while any other form of race reduces even this safe load.

The Small Capacity is due to the concentration of load on a minute surface of contact, ordinarily called a "Point." A radial bearing employing rollers increases this contact surface enormously, at the same time increasing the value of the bearing as a load carrier. This is the result of what is known as "Line Contact."

To Carry Radial Loads without introducing wedge action and destructive internal stresses (as in present forms of tapered rollers or "Cup and Cone" balls) it is essential that the axis of rotation of the rollers or balls be always parallel to the axis of the shaft.

Destroy this Feature—essential to correct operation—and the balls will spin and wear. Solid and rigid rollers will get out of line and bind, causing either increased friction or complete failure of the bearing. Accurate workmanship and durable material in bearing construction are both sufficiently rare and costly without adding the burden of improper design.

Hyatt Flexible Rollers combine the advantages of Line Contact and ability to maintain practical alignment without increase of friction or wear in the bearing.

Hartford Pointers—No. 4

Greater Safety—and Easy Riding

A BROKEN SPRING encourages trouble—invites disaster. Without proper prevention spring breakage is ever a possibility.

Imperfect traction results in loss of steering control. A car that is subject to jumping—whose wheels do not cling to terra firma—is hard to drive, difficult to steer.

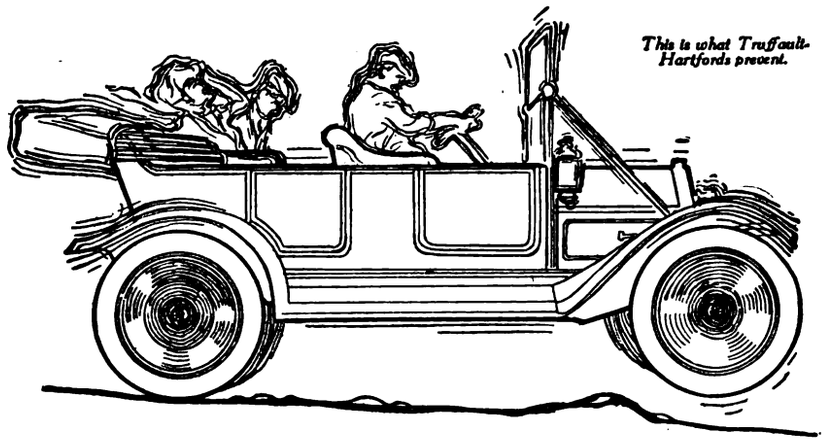
A bursting tire is the dread of every motorist, not only because of the expense it involves, but the danger it so surely incurs.

Spring breakage is virtually an impossibility when the car is equipped with the

Truffault-Hartford SHOCK ABSORBER

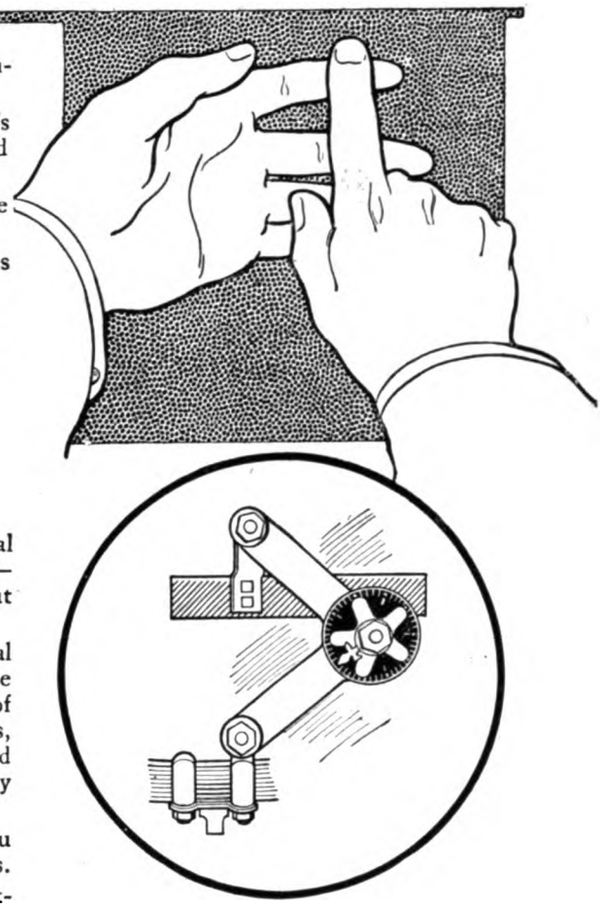
and the other dangers are in a large measure prevented.

The Truffault-Hartford maintains an even, constant, frictional resistance to the excessive contraction and expansion of the spring—such a resistance as invariably holds the spring in perfect control but does not lessen, in the least, its flexibility.



Thus the jolt and jar are eliminated and spring action made normal under all conditions of road. Thus the springs are saved from all undue strain. Thus the wheels are kept constantly on the ground; loss of traction overcome, and the destructive bouncing of tires avoided. Thus, too, the vibration which accompanies excessive spring action is reduced to a minimum; wear and tear on engine and parts becoming perceptibly less.

These, then, are the advantages in both Safety and Economy that you gain by equipping your car with Truffault-Hartford Shock Absorbers.



But, consider also the greater car-comfort that the Truffault-Hartford makes possible—consider how much it means to you and those who ride with you, to be able to travel over rough stretches of road without reduced speed and with neither jolt nor jar. Truffault-Hartford equipment will make you proud of the riding-qualities of your car—will improve them beyond your expectations.

The first cost of Truffault-Hartford equipment is practically its only cost. Readjustment is seldom necessary and may be made with a wrench. As for durability, Truffault-Hartfords will outlive the car itself. With each set is furnished a blue print showing the correct method of attachment for the make, year and model of your particular car. Built in four sizes: $60.00, $45.00, $25.00, $15.00, per set of four.

24 automobile manufacturers include the Truffault-Hartford in the regular equipment of every car they produce.

This is what Truffault-Hartfords prevent.

Talk to your dealer about this device. He is ready to answer any questions you may have. Investigation does not involve any obligation whatsoever. Our interesting catalog is worthy of your attention. Let us send *you* a copy.

Spring action being necessary to secure easy riding, auto owners should avoid so called shock absorbers working on the **eccentric** cam and **wedging** principles. Such devices limit the play of the springs, creating a condition undesirable, if not actually dangerous.

Make Money Selling Lippard-Stewart Motor Delivery Cars

Scores of live dealers throughout the country are realizing the big money-making possibilities of handling Lippard-Stewart delivery cars.

They have discovered that this car—the first high-grade commercial car at a low price—is just what merchants have been looking for.

They have found that the many up-to-date, exclusive features of the Lippard-Stewart make it a quick and easy seller. Everywhere this car appears, it immediately attracts favorable attention and brings orders.

Our business is showing a wonderful increase each month. Our dealers all predict a record year.

Here Is Your Opportunity

The commercial car field affords the biggest opportunities nowadays. In this field the light delivery car offers the widest market; and among light commercial cars none is such an attractive selling proposition as the Lippard-Stewart.

Consider the following reasons why this car will prove a profitable line to handle:

1. Lippard-Stewart cars know no "seasons." They are always needed and sell just as readily in winter as in summer.
2. Fancy showrooms unnecessary to sell Lippard-Stewart delivery cars. The service and utility of these cars are enough to win the orders.
3. It is easy to show merchants how Lippard-Stewart delivery cars will pay for themselves out of the savings they effect over horse delivery.
4. No trouble to locate prospects for Lippard-Stewart cars. Every merchant who delivers goods is a prospective buyer.
5. You can sell several cars at once by the same effort that would sell one pleasure car. Satisfactory service makes repeat orders easy.
6. Lippard-Stewart cars are the first light delivery cars to embody all the latest and best features, such as:

Four-Cylinder Monobloc Motor.	Bosch Magneto Single Ignition.
Selective Transmission.	Thermo-Syphon Cooling.
Multiple Disc Clutch.	Special Spring Suspension.
Special Timken Rear Axle.	Every Part Accessible.
Left-Hand Steering.	Handsome Lines—Beautiful Finish.

We Want More Dealers

We still have some choice territory open for dealers. Perhaps your city is one where we are not yet represented. If so, do not overlook this opportunity. Fill out and mail the attached coupon for our dealers' proposition. Let us help you make this the most profitable year you have had.

Sending in the coupon may be the means of doubling your profits for this year.

The *Little* Fellows Can't *Do* It

New York City has a $5,000,000 library. It's the *finest* in the *world*, but it cost New Yorkers only one dollar apiece. If a city of a million people tried to raise a building as large, it would cost each citizen five times as much.

The same principle holds in the speedometer business.

The Stewart factory makes *four* out of *five* speedometers in use. The population of Stewart users is so large that we can make the best speedometer in the world and ask the *least* for it.

For *work* or for *looks* the Stewart is *best*. Scant sales at high price is the tale of the rest.

Magnetic principle—jewel bearings—wearing parts hardened and polished; open dial—large figures, easily read—absolutely accurate; 100,000-mile season odometer, 100-mile trip register, can be reset to any tenth of a mile. Guaranteed for five years. Strongest flexible shaft—drop forged swivel joint—noiseless gears.

"ALWAYS ON THE JOB."

Speedometers $15 to $30
Clock Combinations, $45 to $70

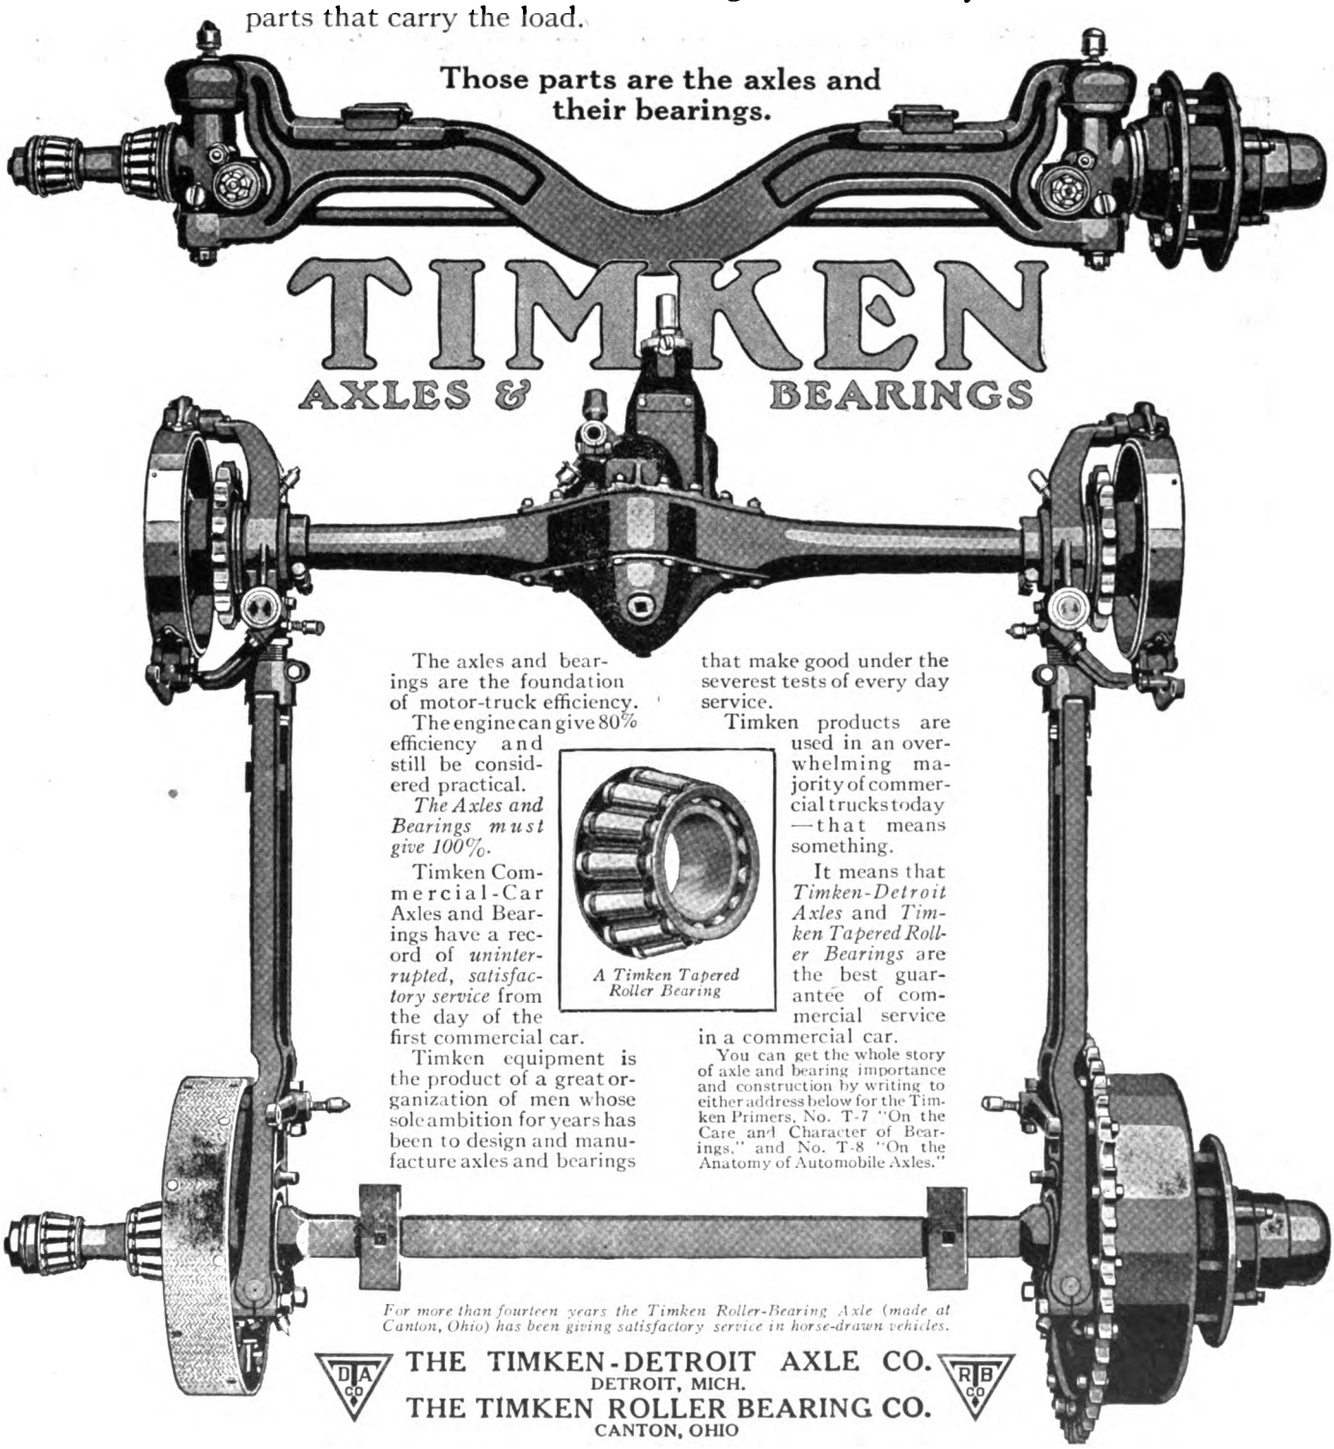
What Makes the Commercial Car a Practical Possibility?



Strength and flexibility in the parts that carry the load.

To be commercial a motor-truck must carry its load in a commercial way.

It must give uninterrupted service—good service—over any road—ten hours a day—*every working day* in the year.

To do this it must have strength and flexibility in the parts that carry the load.

Those parts are the axles and their bearings.

TIMKEN AXLES & BEARINGS

The axles and bearings are the foundation of motor-truck efficiency.

The engine can give 80% efficiency and still be considered practical.

The Axles and Bearings must give 100%.

Timken Commercial-Car Axles and Bearings have a record of *uninterrupted, satisfactory service* from the day of the first commercial car.

Timken equipment is the product of a great organization of men whose sole ambition for years has been to design and manufacture axles and bearings that make good under the severest tests of every day service.

A Timken Tapered Roller Bearing

Timken products are used in an overwhelming majority of commercial trucks today—that means something.

It means that *Timken-Detroit Axles* and *Timken Tapered Roller Bearings* are the best guarantee of commercial service in a commercial car.

You can get the whole story of axle and bearing importance and construction by writing to either address below for the Timken Primers, No. T-7 "On the Care and Character of Bearings," and No. T-8 "On the Anatomy of Automobile Axles."

For more than fourteen years the Timken Roller-Bearing Axle (made at Canton, Ohio) has been giving satisfactory service in horse-drawn vehicles.

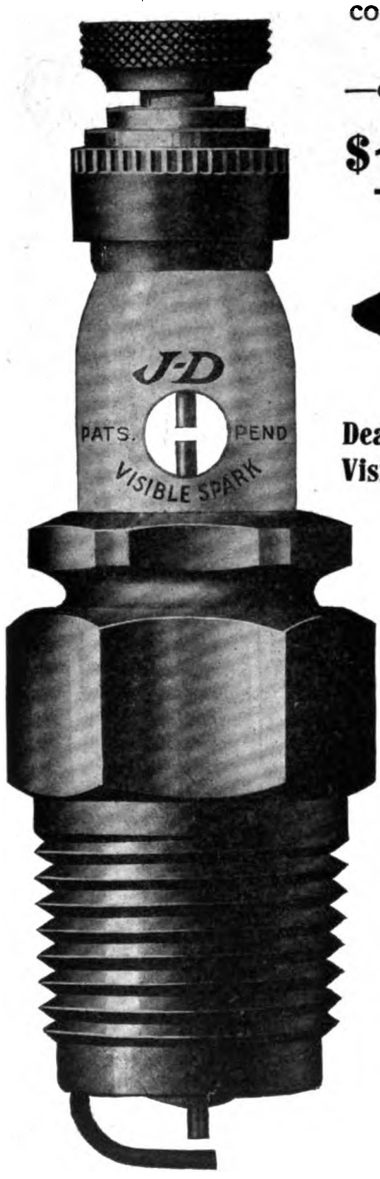
One Look Tells Everything



The JEFFERY-DEWITT CO. DETROIT, MICH. Visible Spark Plug lays bare all ignition troubles

The "visible gap" is an open "window" giving you a full view of the internal workings of your spark plug.

If the spark is seen jumping the gap, look for your trouble between the gap and sparking point.

If there is no spark in the gap, your trouble is behind the plug—in Magneto, or batteries, or coil, or wiring.

But for the "visible gap" it would take you many precious minutes —often hours—to locate the seat of trouble.

$1.00 Buys this great new Spark Plug

Indicates in which direction trouble lies.
Facilitates timing of engine.
Intensifies spark in cylinders.
Consumes only minimum current.
Gap adjustable—can be closed entirely.
By widening gap plug cleans itself.
Permits regulating spark for any cylinder.
Costs same as any good plug—$1.00.

Dealers will find J. D. Visible in greatest demand

Visible Idea Worked Out Perfectly for the First Time

The "visible gap" feature, so far as being incorporated in a plug, has always seemed as far away as perpetual motion. The visible feature has been marketed in a separate device for years, but this is the only plug in which this important visible feature is actually embodied.

It is simple. Merely a hole in the porcelain and a spiral action to regulate width of the gap in the central electrode which carries the current.

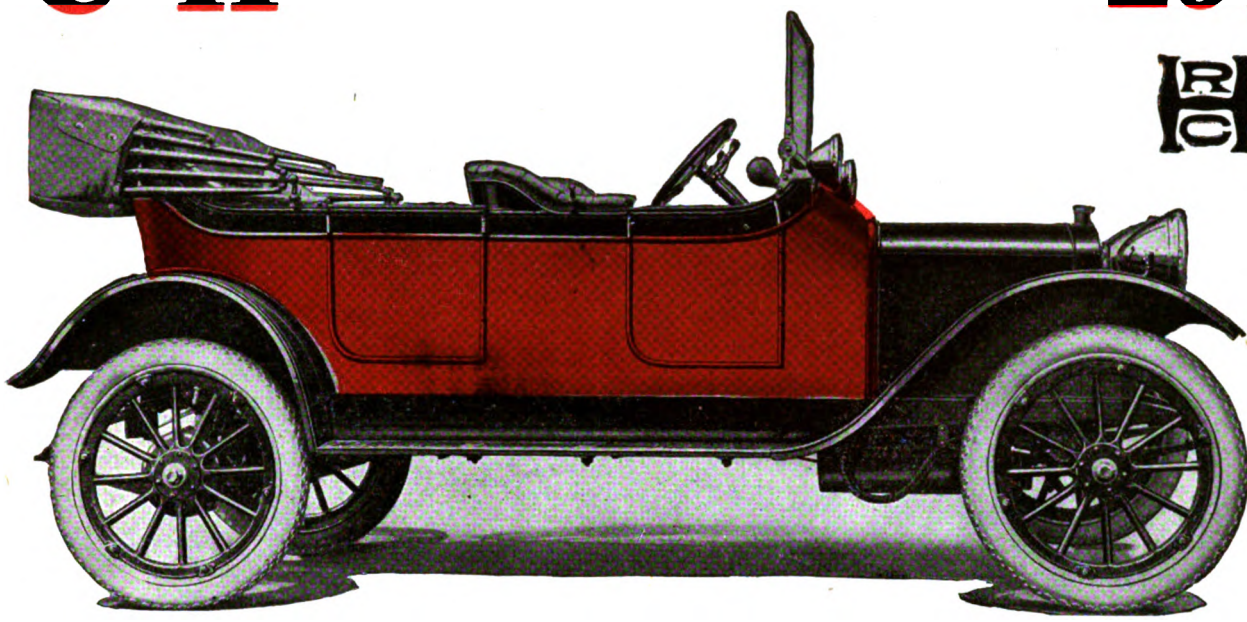
The hole in no way lessens the strength of the plug, and the current in jumping the "visible gap" loses none of its efficiency. On the other hand it intensifies the spark at the gap in the cylinder.

Additional prestige is lent the J. D. Visible Spark Plug by the fact that it is being introduced by the largest manufacturers of spark plugs in the world. We are exclusively manufacturers of spark plugs; we make millions of them each year.

The J. D. Spark Plug was a famous plug before it was improved by the visible feature. It combines finest workmanship, best materials and simplest designs.

Every part of this plug is made in our factory—even the porcelain being produced in our own potteries from clays and other ingredients imported from Europe.

This unequivocal guarantee goes with all our spark plugs:



"Your money back or a new plug if you are not satisfied."

If your dealer hasn't the J. D. Visible yet, send your money direct to us for a set, specifying size wanted and make of car, and we will ship them postpaid. Remember, the J. D. Visible Plug is $1.00. Our literature on ignition free for the asking.

R-C-H Announcement 1913

R-C-H "Twenty-Five"

We are determined to build the best all-'round five-passenger touring car in the world and sell it, completely equipped, for

$900

f. o. b. DETROIT

The Car

Wheelbase— 110 inches.

Motor— Long-stroke; 4 cylinders cast en bloc; 3¼ inch bore, 5-inch stroke. Two-bearing crank shaft. Timing gears and valves enclosed. Three-point suspension.

Drive— **Left Side.** Irreversible worm gear, 16-inch steering wheel. Spark and throttle control on steering column.

Control— **Center Lever** operated through H-plate integral with universal joint housing just below. Hand-lever emergency brake at driver's right. Clutch pedal operated by left foot. Service brake operated by right foot. Foot accelerator in connection with hand throttle.

Springs— Front, semi-elliptic; rear, full elliptic and mounted on swivel seats.

Frame— Pressed steel channel.

Axles— Front, I-beam, drop-forged; rear, semi-floating type.

Transmission— Three speeds forward and reverse; sliding gear, selective type.

Construction— Drop-forgings wherever practicable; chrome nickel steel used throughout all shafts and gears in the transmission and rear axle; high carbon manganese steel in all parts requiring special stiffness.

Body— Full 5-passenger English type; extra wide seats; 10-inch seat cushions specially upholstered.

Wheels— Artillery type.

The Equipment

Non-skid tires—32 x 3½.

12-inch Bullet electric head light with double parabolic lens.

6-inch Bullet electric side lights with parabolic lens.

Bosch Magneto.

Warner Auto-Meter.

Demountable rims.

Extra rim and holders.

Tally-ho horn.

Jiffy curtains—up or down instantaneously.

Top and top cover.

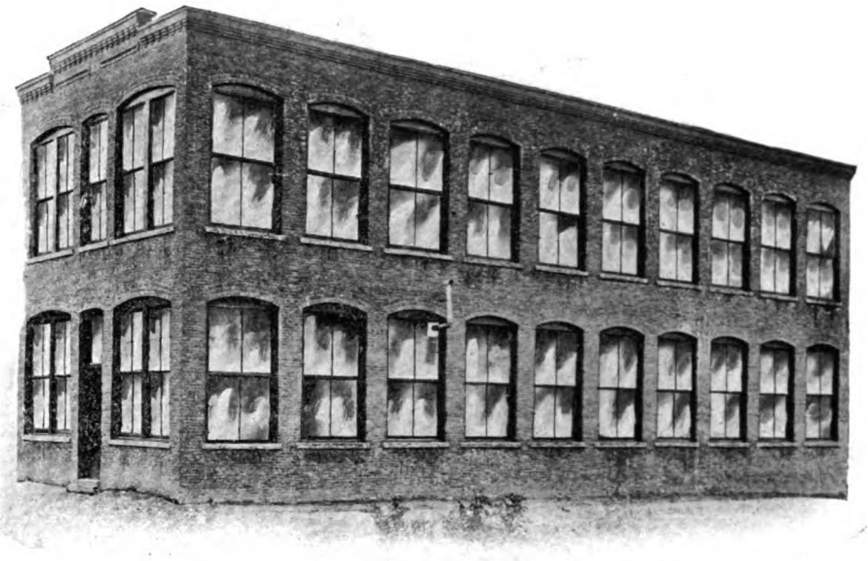
Windshield.

Rear view mirror.

Tool-kit, Jack, Tire Repair Kit, Pump.

Robe Rail.

WE invite prospective motor car buyers to call at the nearest R-C-H branch or dealer; to study R-C-H construction and equipment; and, more than all to ride in the car and determine for themselves its running qualities and ease of operation. Descriptive folder and name of nearest dealer mailed on request.



Correspondence invited from responsible dealers in any vacant territory.

Chalmers "30" Roadster
Self-Starting $1400

This monogram on the radiator stands for all you can ask in a motor car

To Owners of High-Priced Motor Cars

A Chalmers Suggestion

IT is often uneconomical to use your big, luxurious touring car in the routine of business.

Don't you really think you need a light roadster to supplement the service of your big touring car? You have a lot of "running around" to do which can be more quickly and cheaply done in a smaller, handier car.

Here is just such a car—the new self-starting Chalmers "30" Roadster, $1400, fully equipped.

This roadster is designed and built to suit the needs of the busy man. It is speedy, roomy, comfortable, easy to handle, economical and good to look at.

Note These Alluring Features

The body is painted an attractive blue with black mouldings. Hood and chassis, including wheels, are black with blue striping.

The seat is generously wide for two passengers. Gear shift and brake levers are inside the low-hung body.

The stylish, close-fitting top is of brown duck with side curtains and storm front.

This is just the car for business use—a car you can keep down town all day, where the size and weight of your touring car are a handicap and a useless luxury.

Leave Your Big Car for the Family

How often when you have been using the big car, has your wife or daughter wanted it for shopping or calls? A Chalmers roadster would have been a convenience and an economy then—and in a hundred other cases.

The new Chalmers roadster is light in weight; easy to control; the 104-inch wheel base is just right for handling in city traffic —and the Chalmers self-starter obviates the necessity for cranking.

Can you afford to be without a car of such varied usefulness? The $1400 you invest will be returned to you in time saved, in convenience, in comfort—in one season. The price includes Chalmers self-starter, special top, automatic windshield, Prest-O-Lite tank, gas and oil lamps, horn, tire-inflater, jack, pump, full set of tools, and tire repair outfit.

We would like to have you see this up-to-the-minute car. Won't you arrange with the Chalmers dealer for a demonstration at your convenience?

Chalmers Motor Company, Detroit, Mich.

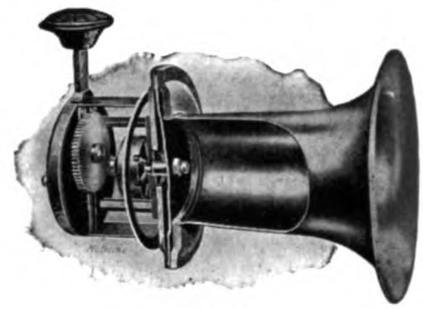
Simplicity

It is largely the simplicity of construction that makes the Long Horn so reliable and dependable. There is nothing to get out of order—nothing to fail in the time of need.

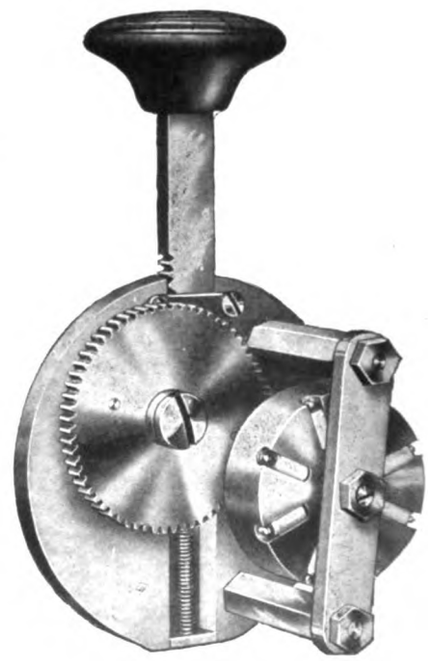
Remember that a warning signal is seldom needed except in an emergency. The successful warning signal can never record a failure. Not once in a thousand times—for that once is sure to be the time you need the warning most.



It's because the Long Horn never fails to warn that it is registering its great success.

If you can press the button the horn will perform its functions.

It is not an electric horn—but the superior to any electric horn (when that electric horn is working.)



No wires to break—no friction pulley to slip—no batteries to give out—no motor to go back on you—no cost of upkeep—its first cost is its last cost.

Have you joined the army of Long Horn representatives yet? Why wait, when the delay means a loss of money to you?

$18.00

THE Durable Dayton

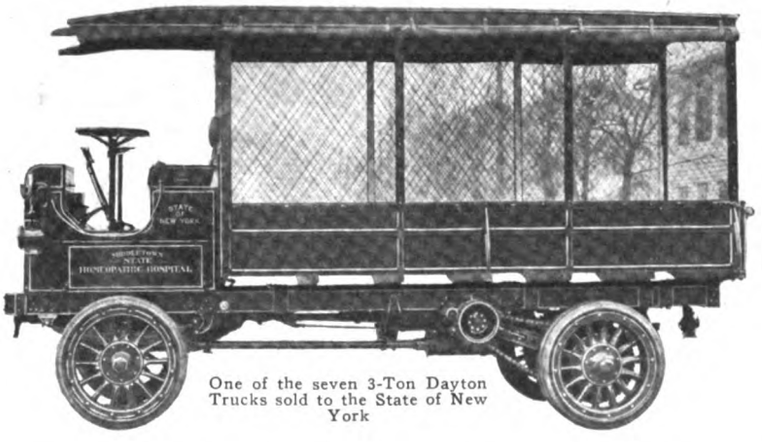
21 Makers of Motor Trucks Competed for the Contract of "New York State"

SEVEN 3-ton DAYTON TRUCKS were recently sold to the State of New York, after keen competition with models of twenty-one different motor truck manufacturers.

After strenuous tests, the State Authorities were convinced of the superiority of design and durability of DAYTON TRUCKS.

Durable Dayton Trucks are made in 2, 3 and 5-ton capacity—designed for hard work, heavy duty and continuous service. In design, construction and workmanship, they cannot be surpassed. In actual working service, they cannot be equalled.

It will at least pay you to investigate the DURABLE DAYTON. Our traffic department will gladly submit interesting data covering your delivery and transportation requirements.



WE DESIRE AGGRESSIVE AND RESPONSIBLE REPRESENTATIVES IN TERRITORY NOT ALREADY CLOSED.

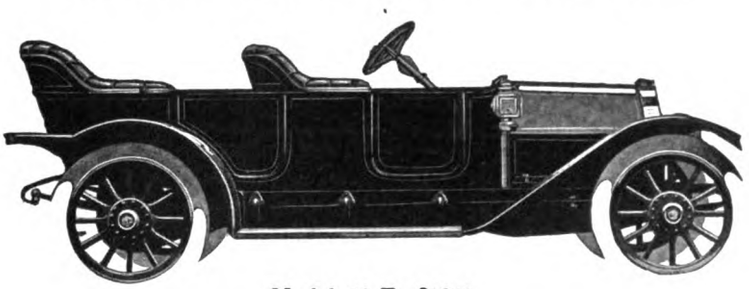
Overland



NEARLY twelve months ago we announced the Overland Model 60 at $1200. We had unbounded faith in it. We looked for it to be the big winner of the season.

The clamor for the Model 60 fails to cease as the season ends. No month has seen us make enough. The value of the car is apparent at sight. The more we make the more we increase the demand.

No car of similar value can be found anywhere at the price. Under any other name the Model 60 would cost $1500. Production methods must regulate price. Ours are 95 per cent. efficient. They bring you the Model 60 at a bottom price.

Model 60 is representative of the line it pays each dealer and owner to watch. Write for book I-46.

The Willys-Overland Company, Toledo, Ohio

Model 60-T—$1200

Wheel base, 111 inches; body, 5-passenger fore-door touring; motor 4⅛ x 4½; horsepower, 35; Remy magneto; tires, 34 x 4 inch Q. D.; equipment, three oil lamps in black and brass finish, two gas lamps, horn and generator. Self-Starter, $20 extra.

THE MOTOR WORLD

Vol. XXXII New York, U. S. A., Thursday, June 27, 1912. No. 1

AMPLEX THOROUGHLY REORGANIZED

Mead Assumes Presidency and Two-Cycle Motor Abandoned—Four-Cycle "Six" and Knight "Four" Replace it.

When T. C. Starritt and H. M. Hovey, the Detroiters who three weeks ago took over the assets and liabilities of the Simplex Motor Car Co., of Mishawaka, Ind., set about reorganizing it under the style Amplex Motor Car Co., they not only reached out in an unexpected direction for the man to assume direction of its affairs but decided to cast out even the two-cycle engine which so long has constituted the Amplex feature.

The man they have chosen to carry on the work is none other than W. J. Mead, vice-president and general manager of the Olds Motor Works, of Lansing, Mich., and one of the vice-presidents of the General Motors Co., of which the Olds establishment is a part. Mead has assumed the presidency and general management of the Amplex company and, vested with full power, he is losing no time in shaping its affairs in new and more profitable directions, bringing to bear the varied experience he acquired, first with the Buick Motor Co., which he joined in 1905, and later with the Olds Motor Works and the General Motors Co. itself, in whose councils he stood high. He has not yet completed the organization of his staff, but it has been definitely settled that the two-cycle motor will be displaced and that the sales and general offices of the Amplex company will be located in Chicago and not in the factory at Mishawaka, which means, of course, that Mead's headquarters will be located in Chicago.

The new productions of the new company will continue to bear the name Amplex, but there the resemblance to the models of the old company will end, for, as stated, the two-cycle engine hitherto associated with the name has been cast out bodily and for it will be substituted not only a six-cylinder, long-stroke, four-cycle, poppet valve engine, but there also will be included in the Amplex line a Knight-engined model, of which latter, however, only a limited number will be manufactured. That they will be high grade productions goes almost without the saying.

Hutchinson Assumes Olds' Management.

To fill the vacancy created by the resignation of W. J. Mead, who is to become president of the Amplex Motor Car Co., of Mishawaka, Ind., Oliver C. Hutchinson has been promoted to the office of vice-president and general manager of the Olds Motor Works, Lansing, Mich. Hutchinson, who for several years served as sales manager for Thomas B. Jeffery & Co., of Kenosha, Wis., was appointed manager of the Marquette company, of Detroit, some two years ago and the measure of his success with the Marquette car, which is the newest in the General Motors group, is best evidenced by his elevation to importance in the pioneer Olds establishment.

Speedwell to Produce Knight Model.

Although the car has been in use for several months, it just has become definitely known that the Speedwell Motor Car Co., of Dayton, O., will include a Knight-engined model in its forthcoming productions. It will make use not only of the Knight engine but a worm gear also and will list at $4,000. As the Speedwell company is not a Knight licensee, it naturally will purchase its engines from outside sources and put to them such extra touches as its experience indicates are necessary or advisable. A six-cylinder car also will be added to the Speedwell line, which serves as the best answer to unfounded reports that the company purposed abandoning pleasure cars for the manufacture of motor trucks.

Studebaker Shares Now "On 'Change."

The governors of the New York Stock Exchange yesterday approved the listing of the shares of the Studebaker Corporation. Hitherto the stock has been dealt in only on the curb market.

GASOLENE MOUNTS STILL HIGHER

Regular Monthly Increase Brings it to 16 Cents, an Advance of 78 Per Cent.—Meanwhile Quality Deteriorates.

Good old Supply and Demand, who are the best friends ever had by any corporation that ever raised a price, have continued their labors for the Standard Oil Co. Yesterday, 26th inst., they again tested their inflating apparatus and, presto! the price of gasolene at once rose to 16 cents per gallon, which, according to some statisticians, is the highest quotation since the Civil war; it certainly is the highest since Standard Oil's memorable "engagement" with Uncle Sam last year, which decided it to go through the motions of "dissolving." Only about six months ago the fuel was selling at 9 cents per gallon.

Supply and Demand always have worked industriously for the Standard Oil Co., but never more industriously than during the past half-year, within which period the price of automobile fuel has been advanced 78 per cent. They are such skillful workers that few can follow their operations, but apparently they have decided that an advance of about 1 cent per gallon per month is best for the health and enormous dividends of their particular patron, and they have acted accordingly. For each month since January last 1 cent has been added to the price; but not always has the increase attained publicity. On May 13th, for instance, it became known that the price had advanced from 13 to 14 cents; on the 25th of the same month it was advanced from 14 to 15 cents, but the latter inflation was so quietly performed that it did not become generally known.

There are those who maintain that even the increase of 78 per cent. but poorly represents the real advance, for these people —and they are numerous—insist that as the price has gone up the quality has gone down; certain it is that once self-respecting automobiles of late have acquired a thirst

Digitized by Google

that requires very much more gasolene to assuage.

Few of those who purchase gasolene are given to testing its quality, but the garage committee of the Long Island Automobile Club has kept track of such things and has found that the gasolene purchased from outside garages is giving 50 per cent. less mileage than the fluid which it purchases and supplies to its members.

At the offices of the Standard Oil Co. they pay a genial gentleman something like $20,000 a year to "explain things" to newspaper men and other callers. His efforts to explain the advance in the price of gasolene are visibly painful, however. The gentleman knows little regarding production and quality, and when price is mentioned he merely presses a button in his interior and, forthwith, Supply and Demand appear on the scene. They are rollicking, good-natured chaps, but unfortunately they are deaf and dumb, and as they appear only to disappear, it requires a magician to find their abiding place.

From other sources saturated with Standard Oil, however, more real information is obtainable, but not concerning prices, which are given to them but to obey. These sources admit that not all of the gasolene sold is "up to test," or of a quality such as once was generally dispensed. But the fault lies, not with Standard Oil fuel, but, if you will believe it, with the fuel supplied by other and smaller companies, some of whom, it is declared, are supplying gasolene which tests but 59°. Standard Oil itself, however, supplies several grades of gasolene. That which is commonly supplied to garages—and which now is sold to them at 16 cents per gallon—is supposed to be about 67°, but no guarantee attaches to it. It is stuff that is commonly known as "autonaphtha" and "stove gasolene." The same article sold in wood barrels to other than garages now stands at 18¾ cents per gallon, and 17 cents in steel barrels; 68° to 70° gasolene in the same receptacles sells for 20 and 18 cents per gallon, and 70°-72° for 21 and 19 cents, but the latter grades are not in general use and are supplied only when specified. These prices are those that prevail since the 1 cent was added yesterday, and which are likely to prevail until Supply and Demand trot out next month.

Failure to File Report Brings Suit.

Because the Auto Robe and Rubber Co., of 13 East 16th street, New York city, failed to file its corporation return for the year 1910, suit for $10,000 is being brought against it in United States District Court for the Southern District of New York. The Federal Government is prosecuting the action.

B. M. O. Truck Changes its Title.

The B. M. O. Motor Truck Co., of Cleveland, O., has changed its name to the Standard Motor Truck Co. The necessary certificate has been filed with the state authorities.

WARM WORDS PASS AT "A" MEETING

Promoters of Pacific Coast "Independence" Turn on Accusers—Many Shares Are Sold but Few Paid for.

Lack of warmth and animation did not characterize the annual meeting of the much-troubled "A" Automobile Co., of Sacramento, Cal., when it occurred last week in the offices of the promoters, Cooke & Remmers, in San Francisco. Three attorneys, representing the dissatisfied stockholders, were present, fortified with the proxies of those whom they represented, but only one of the lawyers was admitted to the meeting, the others being excluded because their proxies were declared to be not in proper form; the one who obtained admission, however, made things sufficiently interesting.

F. T. Cooke presided at the meeting, but most of the talking was done by his partner, Remmers, who got into several violent altercations with M. L. Haines, the attorney who obtained admission and who had been seeking to bring about the arrest of the promoters on a charge of fraud. Remmers, it is stated, several times declared that he would "get" Haines yet. He also referred bitterly to the refusal of the Sacramento Chamber of Commerce to endorse his project and avowed that it would yet regret its action, predicting that within six months "A" automobiles would be running on the streets of Sacramento, as visible evidence that the Pacific Coast can be independent of Eastern factories.

Some 315,000 shares were represented at the meeting, but it was brought out that only 57,610 had been paid for in full. The Cooke-Remmers interests controlled the election, however, and chose directors as follows: E. C. Collins, F. T. Cooke and N. C. Norton of San Francisco; E. C. Schelhaus of San Francisco; J. F. Cooke of Sacramento; James Hall of Watsonville, and Charles Kraus of Santa Rosa. They also were instrumental in having introduced a resolution aimed at the dissatisfied stockholders and the newspapers which had given publicity to "A" affairs, and which also declared that Cooke and Remmers "have always done their duty and have been honest and conscientious, and their integrity is believed in."

While the meeting was in progress, Remmers was under citation for contempt of court for ignoring a subpoena to give a deposition in one of the several suits brought by dissatisfied stockholders.

Gillard Goes Higher on Pullman Ladder.

After serving three years in a minor capacity, Ernest T. Gillard has been promoted to the post of factory manager of the Pullman Motor Car Co., of York, Pa. Although but twenty-eight years of age, Gillard, who is a French engineer, has enjoyed extensive experience, having been attached to the engineering staffs of the Renault, Darracq and Moto Bloc establishments, Gillard's uncle being president of the last named company. Gillard has to his credit also the highest scholarship, won at the Geneva Institute in Switzerland, both as a mechanical and technical engineer. The Pullman line for 1913, however, will be marked by little, if any, change. One model will be eliminated, but the other current productions were so late in making their appearance that President O'Connor states that they were to all intents and purposes designed for the 1913 market.

"Clink of Gold" Nets 26 Per Cent.

According to the report of the receiver, the general creditors of the American Automobile Mfg. Co., of New Albany, Ind., which in grandiloquent style sounded the "clink of gold" in the ears of investors, will receive a dividend of 26 per cent. as a result of the recent sale of the company's property. The general creditors will include six stockholders who paid the 20 per cent. assessment on their shares which was levied several months ago. Other stockholders will receive nothing. When the property was sold by the receiver it was bid in by L. A. Boli, one of the heads of the old company, who represented the American Automobile Corporation, which is designed to continue the business. He paid $17,500 for the plant, and also assumed the mortgage and certain taxes and small claims which brought the price to about $45,000. The American Automobile Mfg. Co. was woven around the Jonz car, which was born in Nebraska, where, however, it failed to flourish. Removal to Indiana did not add to its health, despite one of the most florid stock selling campaigns ever instituted.

Sub-Dealership Lawsuit Compromised.

Although the basis of settlement was not made public, the suit brought against Frederick and Nicholas Koenig, Jr., brothers, of Tarrytown, N. Y., by the Overland Sales Co., of New York City, and later conducted with the Silver Motor Co. as complainant, was compromised and settled out of court late last week as it was about due for trial in Supreme Court for New York County. The action was based upon a claim that, after signing up as Overland sub-dealers under the complaining company the Koenig brothers did not live up to their contract, and on notes and other matters owed the complainant $948.93. The change of complainants was due to the fact that the Overland Sales Co. has become the C. T. Silver Motor Co.

Kingman Returns, His Health Restored.

After an absence of many months in Europe, in search of health, John A. Kingman, advertising manager of the Locomobile Co. of America, with which he has been connected since its organization in 1899, returned home late last week. He is again at his desk and in good health.

FORD "GOES FOR" A PRICE CUTTER

Charging Fraud and Deceit and Unfair Dealing, Asks $50,000 Damages—Patent Rights Also Brought to Bear.

Trifling with the price of Ford cars has resulted in the Union Motor Sales Co., of Dayton, O., being called into the Federal court in Cincinnati to explain its action and to defend itself in a suit for $50,000 damages instituted by the Ford Motor Co., of Detroit. The Sales company is composed of Lucien A. Howard, J. Carl Horton, Earl S. Sorsley and William Yokum, all of whom are named in the complaint.

The Union Sales company is one of the kind which has professed to be able to supply cars and parts thereof, Fords among others, at less than list prices; but, apparently as a measure of self-protection, the Dayton institution has required that all prospective purchasers of cars acquire a share of its stock, which was sold for the more or less modest sum of $10.

In its complaint, the Ford company alleges that it is possible only by fraud and deceit for other than its own licensees to procure its cars and other parts, and that the Union company has employed this means in violation of the Ford patent and other rights and to the damage of its business.

Alleging unfair business dealing in violation of its patent rights, and in addition to asking for $50,000 damages, the Ford company asks for the usual injunction and accounting. July 1st has been set as the date for hearing arguments, and as Ford's method of attack includes some unusual points, the result cannot fail to prove of widespread importance.

Want Money Back from "Auto Owners."

Early J. Speck and P. B. Gill, of Cleveland, O., are two more of the many men who have had to do with so-called autobile owners' organizations who have repented of their bargains. As a result of their repentance, they have instituted suit in that city to recover $2,000, which they say they have invested in the Auto Owners' Association, which they further allege promised them commissions on all membership stock sold and a percentage of the profits accrued from the vulcanizing operations of the so-called association's Cleveland branch at 2362 Euclid avenue, of which they were in charge. In their complaint, they allege that the promises were not carried out.

Castle Lamp to Go to Kalamazoo.

Richmond, Ind., which fancied that it had secured the Castle Lamp Co., was too previous in sending out reports to that effect. The Richmond deal fell through, and, instead, the Castle Lamp Co., which at present is located in Amesbury, Mass., will remove to Battle Creek, Mich. where it has purchased outright a large, modern, fireproof factory building, affording 75,000 square feet of floor space. It is the intention of the Castle company, which is one of John N. Willy's properties, to so equip the structure that it will stand as one of the best appointed automobile lamp producing plants in the country. Fred E. Castle, the active head of the business, will remove to Battle Creek and assume personal charge of operations.

Ford to Enlarge its Canadian Plant.

Reflecting the prosperity of the American company, the Ford Motor Co. of Canada has purchased a site adjoining its plant in Walkerville, Ont., on which immediately will be erected a four-story structure 75 x 510 feet. When this building is completed, the Ford Canadian plant will have 70,000 square feet of floor space, which will permit of the employment of about 2,000 men. The new structure will be so equipped as to permit of the complete manufacture of Ford cars, and thereby lessen the volume of assembling which now is done and make the Canadian establishment a factory in the full sense of the word.

Miss Knight Forms New York Company.

To better advance the interests of the K-D crescent valve motor, the K-D Motor Co. has been incorporated under the laws of New York with an authorized capital of $100,000. Miss M. E. Knight, the inventor of the motor, is president of the new company; Mrs. A. M. Davidson, the vice-president, and Miss B. M. Davidson, secretary and treasurer. For the time being, the offices of the company will remain in Boston, but headquarters shortly will be established in New York.

Hoyt Retires from Pope Directorate.

Colgate Hoyt, the New York banker, has resigned as a director of the Pope Mfg. Co., of Hartford, Conn. His resignation was due wholly to the fact that the meetings of the board of directors now are held in Hartford instead of New York, and that he cannot find it convenient to make the journeys between the two cities which his attendance requires.

Siebert Prepares to Build More Trucks.

Fred L. Siebert, a Toledo (O.) carriage maker who has been building motor trucks on a small scale, is making ready to enlarge the latter department of his business. To that end he has secured the necessary permit to erect a three-story factory, 75 x 118 feet, on Southard street.

Receiver Named for Flint Body Company.

Robert H. Cook, vice-president and secretary of the Flint Body Co., of Flint, Mich., has been appointed receiver for that concern. The company, capitalized at $50,000, was incorporated January 1, 1909. William B. Stewart, president and treasurer, is also the principal stockholder.

HOT SHOT FROM GREASE GUN MAKER

Rubly Has Judgment Reopened and Throws Light on "35%" Methods—"Export Order" Termed "Trick and Device."

Although on May 25th last the 35% Automobile Supply Co., of New York, obtained a judgment in the Supreme Court for New York County for $2,383.30 against William Rubly, of Tuckahoe, N. Y., it has not yet collected the money. It is possible that it may never collect it; for, on the application of Rubly, the case has been reopened and he has set up a counter claim for $44,000. His amended answer is of the sort that indicates that his fighting blood is up and throws light on the ways of the 35% people.

It makes it appear that when judgment against Rubly was entered the suit had dragged 15 months before it came to trial, the 35% company becoming insistent when, in the picturesque language of Rubly's new lawyer, Holmes Jones, which is on file in court, the plaintiff knew "there was crape on the defendant's doorbell," which is designed to convey that when the case was called for trial, Rubly, because of the death of his mother, was unable to put in an appearance.

The action is one of several which grew out of the more or less remarkable contract whereby the 35% company, in return for specified sums accepted in the form of merchandise, agreed to advertise the wares in a so-called monthly catalog. Rubly, who manufactures grease guns, was one of those who signed the agreement, but he states in his amended answer that it was represented to him that the monthly catalog would be "a booklet" of neat, attractive and dignified appearance, "printed on good, heavy paper" and such as ordinarily would be preserved for reference. He further alleges that he was assured that it would have a circulation of not less than 60,000 copies per month in all parts of the United States and Canada, and that at least 5,000 copies would be mailed to dealers. He was told also, he says, that the number of those whose goods would be represented in the catalog would be limited to eight or nine, and was shown what purported to be a contract with George A. Haws and two other manufacturers, apparently as evidence of the 35 percenters' "good faith." When the so-called booklet appeared and Rubly found it to be merely a handbill, printed on cheap paper and offering for sale 60 or 70 different articles instead of the eight or nine, none of which were made by George A. Haws, and having been informed that the handbill did not enjoy a good reputation and was not given the circulation claimed for it, and after complaining unavailingly of the quality of the "handbill," he ordered the contract canceled and notified the 35% Automobile Supply Co. to discontinue ex-

Digitized by Google

hibiting or printing any advertisement of the Rubly grease guns.

When this occurred, he had delivered $259 worth of the grease guns under the contract, and part of an order for 1,250, to the value of $2,106, which order, Rubly alleges, the 35% company represented was designed for export, in order to permit them to be sold at the jobbers' price. This alleged export order, however, Rubly describes as a "trick and device" and he, therefore, refused to complete it and the 35% company in turn refused to pay his bill.

Acting under his right as the owner of patent No. 966,861, covering his grease gun, Rubly states that at the time he entered into the contract with the 35% Automobile Supply Co. he fixed the list price at which the grease guns were to be sold at retail and the discount which was to be given to dealers. He claims, however, that the 35% company sold his grease guns at much less than the agreed price "with intent to injure, defraud, damage and destroy his market in the United States," and thereby lost to him a contract into which he had entered with a responsible corporation and which provided for the purchase by the latter of at least 5,000 grease guns per year during the life of the patent. For this loss and for other damages sustained, Rubly sets up a counterclaim of $44,000.

The Supreme Court having granted Rubly's petition to reopen the suit, it has been restored to the calendar for trial.

Shelbyville Demands Return of Property.

Trustees of the Citizens' Industrial Association, of Shelbyville, Ind., have filed suit against the Clark Motor Car Co., of that city, for liquidated damages and foreclosure of mortgage, demanding $26,000. The plaintiff asks the title to land and a manufacturing plant turned over to the company two years ago. It is alleged that the company agreed to employ one hundred men for five years, beginning ninety days after the plant was in operation, and has failed to keep the agreement, and has been closed for three months. The efforts of J. Oscar Hall, as trustee in bankruptcy for the Clark company, to recover $7,955 from the wreck came to naught, the suit, which he brought against the Farmers' National Bank, of Shelbyville, to recover that amount having been dismissed by the Federal Court last week. Hall alleged that the Clark company had paid to the bank $7,955 and thereby made a preferential payment.

Body Builders Overcome at Fire.

Considerable damage was done and three officers of the body building concern, the Gregg-William D. Rogers Co., of Philadelphia, Pa., were overcome by smoke when fire broke out last week in their four story factory, at 1926-34 Arch street. The damage was heavy. The men who had narrow escapes when heavy clouds of smoke suddenly filled the building were Vice-President Eugene C. Everhart. Secretary James C. Rabb and Treasurer Frank W. Shriver.

OVERLAND STAFF IN CONVENTION

No Steam-Roller Methods, but a Formal Program Well Arranged—Play that Lightened Serious Side.

Carrying the real idea involved in the word convention a little closer to its logical conclusion than is usual, the first district manager's convention of the Willys-Overland Co., Toledo, was brought to a successful close on Saturday last, 22d inst. It was in making of the convention a veritable school of instruction in a variety of subjects connected with the manufacturing and marketing of automobiles that the real meaning of the word was more nearly approached and the gathering made of real value to both the officers of the company and the district managers who convened and enjoyed the hospitality of the company at the convention hall in the big Toledo factory.

Three days were spent by the body of department heads and district managers in listening to papers read and words of advice from those who are in a position to see all the field at once and thus choose specifics that will prove of mutual advantage in increasing business. Following "A Word of Welcome" delivered by assistant sales manager C. S. Jameson, on Thursday morning, 20th inst., a trip was made through the big Overland and Kinsey plants. Later, factory manager Harry Shepler addressed the gathering, the subject of his talk being "The Factory and What it is Doing, New and Special Machinery, and What Has Been Accomplished." This was followed by a talk on "Laboratory Tests," by Consulting Engineer Carl Neracher, and the day was rounded out by a speech from assistant sales manager H. B. Harper on "What We Shall Expect of District Managers for 1913 and the Handling of Territory and Dealers." Dinner was served at the Hotel Secor and a theater party closed the day's activities. A very similar program was carried out on Friday and was followed by a smoker at the Overland Club on Maumee Bay.

One of the unusual features of the gathering was the presence of an immense Remy magneto which occupied a prominent place in the Convention Hall. At least it closely resembled a Remy magneto, though in reality it was very far removed from being a spark producing instrument. Despite its highly suggestive appearance, it was nothing other than a water cooler. Whether or not sparkling water was cooled is not a matter of record.

On Saturday the program was much the same, the meeting being addressed by Fred S. Andrews and Martin V. Kelly. Following the addresses, luncheon was served at the Toledo Yacht Club, and afterward motor boats belonging to members of the yacht club were requisitioned and a sail on the lake enjoyed. Following the boat ride, the convention was closed with a banquet at the yacht club.

Taxicab Venture Cost Backer $2,000.

Believing from his own experience with Jersey City trolley cars that a taxicab service would be a paying investment in that place, George Lapp, so the complainants allege, promoted the Hudson City Auto Exchange, and as a result is the debtor in a judgment filed this week by the Diamond Rubber Co. of New York for $2,000 in Supreme Court for New York county. The rubber company claimed that Lapp, stating he was financially interested in the new company, agreed to stand sponsor for its credit with the rubber company to the extent of $2,000. When the bill reached $2,184.55 credit was suspended and action taken to collect $2,000 of the amount from Lapp. Wilbur F. Lyon, a Diamond salesman made affidavit to Lapp's conversation as to his reasons for starting the business, citing the poor trolley service.

Ford, "Sold Up," Refuses Further Orders.

When, early this year, the Ford Motor Co., of Detroit, announced that it would produce 75,000 cars during the current season, it appeared such a tall order as to cause some headshaking in the trade. That the company's faith both in the demand that existed and in its ability to produce such an enormous number of cars was well founded is indicated by the fact that the company has served notice on its dealers and branches that it is utterly impossible for it to accept further orders for delivery previous to September 1st next. The company naturally expresses its regret, but states that neither importunate letters nor visits to the factory will serve to alter the situation or result in a show of favoritism. The Ford company is simply "sold up," and that is all there is to it.

Cleveland Branch for Republic Tires.

The Republic Rubber Co., of Youngstown, O., manufacturer of Republic staggard tread tires, has opened a branch at 5919 Euclid avenue, Cleveland. Ben C. Swineheart, who for the past three years has been head of the truck tire sales department of the company, will have charge.

Mitchell Agency Gets Judgment.

Judgment for $311.34 was secured last week in Supreme Court for New York county against the Morgan-Swan Taxicab Co., of New Rochelle, N. Y., by the Mitchell Motor Co., of New York City. The amount involved was claimed on a note given by the defendant.

Victor Top Reaches Over a Rival.

The Victor Buggy & Auto Top Co., 1545 North Broadway, St. Louis, Mo., has absorbed the business of the L. E. Lueschaw Co., of the same city. The activities of the enlarged company will be devoted to the production of tops, seat covers and cushions.

Niagara Falls, N. Y.—Esco Sales Co., under New York laws, with $10,000 capital; to deal in motor cars. Corporators—Joseph Doysmith, Spencer Parker, Chris Gombart.

Chicago, Ill.—Chicago Tire Filling Co., under Illinois laws, with $2,500 capital; to manufacture tire filler. Corporators—Edgar W. Billard, Fred P. Updike, Clarence L. Jackson.

Syracuse, N. Y.—Mohawk Tire Co., under New York laws, with $6,000 capital; to deal in tires. Corporators—Henry J. Moses, Winifred J. Rice, Clarence B. Rice, all of Syracuse.

Pine Bluff, Ark.—Pine Bluff Motor Car Co., under Arkansas laws, with $1,000 capital; to deal in motor cars. Corporators—John F. Rutherford, C. H. Vaughan, W. J. Lockwood.

Chicago, Ill.—Dearborn Automobile Co., under Illinois laws, with $10,000 capital; to deal in motor cars. Corporators—Sidney Oppenheim, Arthur Rosenthal, John G. Ahrensfield.

San Francisco, Cal.—Arctic Auto Accessory Co., under California laws, with $100,000 capital; to deal in motor supplies. Corporators—G. T. Montgomery, G. B. Keane, A. C. Keane.

Grand Rapids, Mich.—East End Auto Co., under Michigan laws, with $10,000 capital; to deal in motor cars. Corporators—Rial W. McArthur, Walter C. McGrath, Silas B. Sisson.

Lynn, Mass.—Seymour Avenue Garage, Inc., under Massachusetts laws, with $25,000 capital; to operate a garage. Corporators—Charles R. Sibley, John E. Moulton, Ellery Jeffts.

Chicago, Ill.—Scientific Auto Tube Co., under Illinois laws, with $200,000 capital; to manufacture tire tubes. Corporators—Ralph E. Cruzen, Howard W. Lewis, Herschel V. Shepard.

Nashville, Tenn.—American Tire and Vulcanizing Co., under Tennessee laws, with $10,000 capital; to deal in and repair tires, etc. Corporators—J. Brenner Fletcher, H. E. Elliott and others.

Los Angeles, Cal.—Los Angeles Dry Battery Co., under California laws, with $25,000 capital; to manufacture batteries. Corporators—Fritz Heine, Carl Jaeger, Elmer E. Morgan and others.

Newark, N. J.—Newark Auto Truck Mfg. Co., under New Jersey laws, with $500,000 capital; to manufacture commercial motor vehicles. Corporators—L. W. Babbage, H. H. Poole, J. T. Walsh.

Chicago, Ill.—Jones Electric Starter Co., under Illinois laws, with $10,000 capital; to manufacture electric motor starters. Corporators—Charles H. Roth, Edward L. Jones, Gustav A. Roth.

Springfield, Ill.—Stadium Motordrome Co., under Illinois laws, with $24,000 capital; to build and manage a motordrome. Corporators—Jerome J. Cermak, James S. McClellan, Harry Okin.

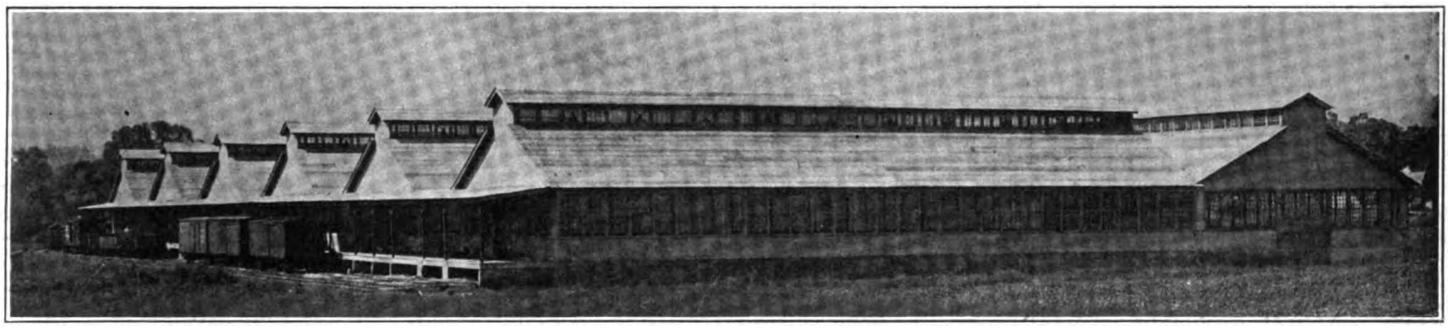
Babylon, N. Y.—Babylon Garage Co., under New York laws, with $500 capital; to operate a garage. Corporators—Charles H. Duryea, William E. Sprague, Annie M. Sprague, all of Babylon.

Newtown, Conn.—Premier Mfg. Co., under Connecticut laws, with $10,000 capital; to manufacture automobile accessories. Corporators — Alfred C. Griscom, Julius Hartwig, Louise Hartwig.

Indianapolis, Ind.—Ideal Motor Car Co., under Indiana laws, with $100,000 capital; to manufacture motor cars. Corporators—H. F. Campbell, H. C. Stutz, W. D. Myers, W. F. Glickert, E. L. Dupree.

Buffalo, N. Y.—Stewart Motor Corporation, under New York laws, with $250,000 capital; to deal in motor cars. Corporators—Charles J. Bork, Bernhard L. Fischer, William Strasmer, all of Buffalo.

Wyoming, Ohio—Wyoming Automobile Co., under Ohio laws, with $10,000 capital; to deal in motor cars. Corporators—Rolla L. Schickner, George Eversman, William Fetzer, P. F. Davidson, C. I. Sears.



Indianapolis, Ind.—Consumers' Carbide Gas Co., under Indiana laws, with $100,000 capital; to manufacture acetylene gas generators—O. K. Stuart, A. J. Schmidt, Robert Clark, C. W. Scoggin, N. J. McGuire.

Columbus, Ohio—Everitt Auto Sales Co., under Ohio laws, with $30,000 capital; to deal in motor cars. Corporators—Horace K. Dobson, Amos F. White, Elmer F. McConah, H. H. Kellenberger, A. W. Raving.

Scituate, Mass.—Egypt Garage and Machine Co., under Massachusetts laws, with $6,000 capital; to operate a garage and machine shop. Corporators—William E. Chafin, Charles M. Litchfield, Charles W. Peare.

Mansfield, Ohio—Mansfield Foundry & Casting Co., under Ohio laws, with $10,000 capital; to operate a foundry. Corporators—Harry L. Krumm, Oscar C. Jacob, Sarah E. Krumm, Helen M. Jacob, Arthur C. Jacob.

New York, N. Y.—Wait's Motor Van & Storage Co., under New York laws, with $25,000 capital; to operate a motor delivery. Corporators — Francis T. Germain, Philip J. Dunn, Louis Burgess, all of 15 Broad street.

PENN MOTOR CAR CO.'S RECENTLY-COMPLETED FACTORY AT NEW CASTLE, PA.

Digitized by Google

Toledo, Ohio—Walker Tire Chain Co., under Ohio laws, with $150,000 capital; to manufacture motor car accessories. Corporators—Henry F. Rohman, Charles A. Newman, Charles P. Eger, A. M. Edwards, George C. Bryce.

New York, N. Y.—Long Acre Garage, Inc., under New York laws, with $1,500 capital; to operate a garage. Corporators—Louis M. Borden, George Gulbranson, both of 384 Fifth avenue; Joseph F. Taylor, 215 Fourth avenue.

Cincinnati, Ohio — Commercial Motor Sales Co., under Ohio laws, with $10,000 capital; to deal in automobiles. Corporators—Walter K. Vosler, George Schorr, Edward H. Hoelscher, William G. Hoelscher and George J. Slaline.

New York, N. Y.—Harlem River Garage and Repair Co., under New York laws, with $900 capital; to operate a garage. Corporators—Edward Meltzer, 55 East 188th street; Frank D. Tice, 1717 Madison avenue; William D. Hookey, 202 West 130th street.

New York, N. Y.—K.-D. Motor Co., under New York laws, with $100,000 capital; to manufacture motors. Corporators—Margaret E. Knight, South Framingham, Mass.; Anna F. Davidson, Beatrice M. Davidson, both of 259 Union avenue, Saratoga Springs, N. Y.

Dayton, O.—Veitch Motor Manufacturing Co., under New York laws, with $200,000 capital; to manufacture motors, motor cars, etc. Corporators—James S. Harris, 126 Liberty street; Percival J. McIntosh, 171 West 70th street; Charles H. Toy, 61 Bainbridge street, Brooklyn.

New York, N. Y.—Henry Engineering Co., under New York laws, with $20,000 capital; to manufacture motor parts. Corporators—George L. Henry, 612 West 138th street; Harry W. Badenhausen, 158 West 2d street, Mount Vernon; Myron F. Hill, 1 Kress Park, New Rochelle.

New York, N. Y.—Creuzbauer Non-Exhaust Motor Co., under New York laws, with $20,000 capital; to manufacture motors. Corporators—William H. Price, 801 Prospect place, Brooklyn; Edgar F. Woodward, 30 Church street; W. Harry Sefton, 168 Montague street, Brooklyn.

Changes of Capital Stock.

Cleveland, Ohio—Westman Motor Truck Co., from $200,000 to $15,000.

Indianapolis, Ind.—Henderson Motor Car Co., from $100,000 to $200,000.

Changes of Corporate Names.

Indianapolis, Ind.—Fisher-Gibson Co. to Gibson Automobile Co. .

Cleveland, Ohio—Park Motor Car Co. to Park Motor and Mfg. Co.

Charleston, S. C.—Robinson Auto Co. to Charleston Motor Sales Co.

Cleveland, Ohio—B. M. O. Motor Truck Co. to Standard Motor Truck Co.

N. A. A. M.'S NEW TRUCK GUARANTEE

Tenure and Spirit the Same but Language More Specific than Former Warranty—How the Two Compare.

After long deliberation and consideration, such as is consistent with the importance of the subject, the National Association of Automobile Manufacturers, Inc., finally has found fitting phraseology for a standard truck guarantee and has adopted it. Though the wording is slightly changed as compared with the tentative form recommended for adoption at the March meeting of truck manufacturers, the spirit is the same. As compared with the former standard guarantee, however, which was adopted May 4, 1910, there is considerable difference, the chief point being that the new guarantee flatly repudiates any responsibility in cases of defects in vehicles that have been driven at speeds in excess of the rated speed, or loaded in excess of the factory rating. The old guarantee did not go to this length.

The period of the guarantee remains unchanged at 90 days, and the old clause withholding guarantees from tires and rims has been extended to cover specifically all trade accessories—"tires, rims, ignition apparatus, lamps, gas tanks, signalling devices, generators, batteries or other trade accessories." Taken as a whole, the new form of guarantee embodies precisely the same ideas as the old one, but it has been found necessary to go into considerable detail in order to avoid misunderstanding. The old guarantee, for instance, covers defects occurring "under normal use and service," while the new warranty goes deeper and defines some of the things that are not considered "normal use and service,"—that is, overloading and overspeeding.

It is recommended by the N. A. A. M. that all manufacturers of commercial vehicles make this their standard guarantee, print it in their catalogues and make it a part of all contracts of sale, either by printing it on the contract or by making specific reference to the guarantee as printed in the catalogue, as the "standard motor truck warranty of the National Association of Automobile Manufacturers, Inc."

The wording of the guarantee is as follows:

We warrant the new motor trucks manufactured by us to be free from defects in material and workmanship, this warranty being limited to making good at our factory any part or parts thereof which shall, within ninety (90) days after delivery of the truck to the original purchaser, be returned to us with transportation charges prepaid, and which our examination shall disclose to our satisfaction to have been thus defective.

This warranty shall not apply to any truck which shall have been repaired or altered outside of our factory in any way, so as, in our judgment, to affect its stability or reliability, nor to any truck which has been operated at a speed exceeding the factory rated speed, or loaded beyond the factory rated load capacity, or which has been the subject of other misuse, negligence or accident.

We make no warranty whatever in respect to tires, rims, ignition apparatus, lamps, gas tanks, signalling devices, generators, batteries or other trade accessories, inasmuch as they are usually warranted separately by their respective manufacturers.

The foregoing obligation to make good any defective parts returned as herein provided is in lieu of all other warranties expressed or implied, and of all other obligations or liabilities on our part, and we neither assume nor authorize any other person to assume for us any other liability in connection with the sale of our trucks.

Lozier's Attitude in Respect to Trucks.

Reports to the effect that the Lozier Motor Co., of Detroit, had decided to abandon the production of trucks until the market acquired a more inviting tone, are denied by President H. A. Lozier himself. Although a Lozier 5-ton truck was exhibited at the national shows last January, it appears that that indication that it had been formall launched was misleading, as Lozier states that his company really never has engaged in truck production. At one time it was hoped to begin deliveries in May, but when that was found to be impossible the Lozier agents were notified that probably no deliveries would be made until December or January next, because of the demands made on the factory by the call for Lozier cars. Apparently some of the Lozier representatives placed a wrong construction on these advices from headquarters by assuming the company had abandoned truck manufacture until further notice.

George H. Day's Son a Typhoid Victim.

Frank P. Day, manager of the Locomobile branch at Atlanta, Ga., died in that city on June 15th of typhoid fever. Day was the son of the late George H. Day, one of the pioneers of the industry and a founder of the Association of Licensed Automobile Manufacturers, and was connected with the Locomobile company for seven years, six of which were spent in the sales department in the factory at Bridgeport, Conn., and the other in Atlanta. Day is survived by his wife.

Rhineland Opens Office in Chicago.

The Rhineland Machine Works Co., of New York, has opened a branch office and stockroom at 1254 Michigan avenue, Chicago. It will be in charge of D. D. Davis, who has represented the Rhineland interests in the Middle West, and will at all times carry a full stock of the imported Rhineland and R. B. F. bearings.

G & J to Erect Another Big Building.

The G & J Tire Co., of Indianapolis, has purchased a site on East Georgia street, adjoining its present factory, on which will be erected a five-story fireproof building, 220 x 170 feet. The estimated cost of the building is $100,000.

THE WEEK'S INCORPORATIONS

A. Korte has opened a garage in Collins, Iowa.

Edgar Behdee has opened a garage in Sladbrook, Ia.

C. W. Spencer has opened a garage in Lake View, Ia.

Boe & Uhlig is the style of a new garage firm in Soldier, Ia.

F. Downen has opened a repair shop and supply store in Carmi, Ill.

B. Martin is about to engage in the garage business in Temple, Tex.

Caywood Bros., of Raymond, Kan., have bought the Pursley & Wolley Garage.

The Flatonia (Tex.) Automobile Co. has bought out the Reliable Auto Repair Shop.

T. P. Scott, of Remsen, Ia., has purchased the automobile business of Hatz & Wictor.

H. F. Vollmer is having a garage built at Grand avenue and 17th street, Los Angeles, Cal.

Fiatt Bros., of Glennville, Minn., are making preparations for the erection of a garage.

The Standard Garage has opened up in Marietta, O.; Clarence Polen is its manager.

Charles Pavik and Dr. Heathman have opened a garage on Main street, Havelock, Iowa.

Frank D. Maltby has opened a garage at 370 West Main street, Battle Creek, Mich.

Frank Seaman of Ashland, Mich., is about to embark as a garageman; his building will be 100 x 60 feet.

Lute Peterson, who recently erected a garage in Buck Grove, Ia., has sold out to Herman Newbaum.

J. M. Dunn and Parker Bennett, of Bakersfield, Cal., have bought the Mason & Flickenger Garage.

Fred H. Williams of Brookline, Mass., is having a garage erected on Beacon street; it will be 150 x 80 feet.

Floy Francis of Moundville, W. Va., has sold his agencies and garage to R. F. Chisler of Fairview, in the same state.

S. Hables of San Francisco, Cal., has secured the Marathon agency, adding one more to the list of dealers in that city.

Stanley Blas of Sacramento, Cal., has launched out as a dealer; he handles the Franklin and is located at 169 M street.

The manufacturers of the Ames car, located at Owensboro, Ky., have opened a branch at 2437 Michigan avenue, Chicago.

G. W. Segrist, of Winner, S. D., has sold his blacksmith shop and garage to Edward E. Grau; the latter will continue the business.

The Stutz Motor Car Co. of San Francisco, Cal., is about to open a branch in Oakland; F. W. Hutch will be the manager.

Newton R. Goltra has opened a garage on Railroad avenue, Greenwich, Conn., under the style Depot Garage and Machine Works.

Charles Miller, proprietor of the Jefferson Garage, Bryan, O., has admitted Emmett C. Fuller, of Logansport, Ind., to partnership.

R. Shaffer, Jr., of Hanford, Cal., has purchased a site on Huffman avenue, on which he will build a garage; it will be 118 x 100 feet.

W. Francis Nutt of Newburgh, N. Y., has accepted plans for a two-story garage and storehouse; it will be erected on Overlook place.

The Columbus (O.) authorities have granted permission to Visla S. Horn to build a garage at 73-79 East Spring street; it will cost $3,000.

John W. Taylor and John T. Rogers are the owners of a new garage which has been opened in Eastman, Ga., at College street and Fifth avenue.

F. H. Alford, of New Britain, Conn., will erect a garage at the rear of the Dickinson Building on Main street; it will be a two-story structure, 40 x 52 feet.

Arthur Wilson, formerly connected with the L. D. McCarthy Automobile Co., in Spokane, Wash., has opened a garage at 228 Riverside avenue; it is 50 x 75 feet.

The General Motors Truck Co., of Detroit, Mich., has opened a branch at 1121-23 Locust street, St. Louis, Mo. A four-story building has been leased for a long term.

The Co-operative Motors Co. has been formed in Long Beach, Cal., and will operate a garage; the manufacture of several truck accessories also may be taken up.

A. A. Petit and William Baxter, formerly proprietors of a horse livery, have secured the Cartercar agency for Atlantic, Ia. They will do business as the Atlantic Cartercar Co.

Under the style Foraker-Dayton Motor Truck Co., an agency for the Durable-Dayton has been opened in Chicago at 1700 Wabash avenue; J. B. Foraker is manager.

Edward Menzie, of Mason City, Ia., has purchased a half interest in the Thoe Auto Co., of Belmond, in the same state, and will remove his residence to the latter place.

John Boos of Detroit, Mich., has secured permission to erect a two-story brick garage and hall on Gratiot avenue, between Townsend and Baldwin streets; it will cost $3,000.

The Burkhard-Crippen Co., in Los Angeles, Cal., is retiring from business. Its quarters at Pico street and Grand avenue have been taken over by the Locomobile branch.

Harry H. Vehon of Minneapolis, Minn., is building a one-story brick and tile garage and store building at 2313-2329 Hennepin avenue; it will represent an outlay of $33,000.

Heintz & Seigel, of 3,582 Third avenue, New York City, have been granted a permit to erect a three-story brick garage at Washington avenue and 169th street; it will cost $45,000.

Floyd Richardson, of Lamont, Ia., formerly a half owner of Richardson Bros.' Garage, has purchased the interest of his brother Clyde and will continue the business alone.

R. W. and Paul J. Sander have leased a garage now being built at Cedar and Rose streets, Owatonna, Minn., by M. S. Alexander and E. T. Winship; they expect to open up July 20.

White & Swearingen is the style of an automobile supply firm which has opened up at 10 East Duval street, Jacksonville, Fla. The members are W. S. White and W. S. Swearingen.

Donald MacVichie of Grand Rapids, Mich., has purchased the garage business of the Ludington Auto and Supply Co. A. F. Keseberg, who is the seller in the transaction, retains his automobile agency.

The Broadway and the Ritter garages in Milton, Pa., have been consolidated under the management of T. E. Spangler. The former will be operated as a garage and the latter establishment as a repair shop.

Shirley W. Rawson and Harvey Brown, under the style Brown-Rawson Garage Co., are about to embark in the automobile business in Gardner, Mass. They will occupy what locally is known as the Knowlton factory.

Following a reorganization of the Washington (Pa.) Automobile Co., Harry M. Newman of Pittsburgh, who acquired an interest, has assumed charge of sales; D. H. Swart remains the executive head of the business.

Permission has been granted to August W. Bohn of 112 Park place, Brooklyn, N.

Digitized by Google

Y., to erect a two-story brick garage at 125th street, Marks avenue and Vanderbilt avenue; it will be 50 x 131 feet and will cost $18,000.

The Cedar Rapids Sales Co. has opened for business in the Iowa city of that name, at Avenue A and Fourth street. It will handle a general line of accessories, having already secured the state rights for the sale of Sturdy spark plugs.

Charles C. Root, an automobile salesman, has petitioned for the appointment of a receiver for the Freeman Automobile Co., of Indianapolis, Ind. He claims he sold $100,000 worth of cars for the concern, but that the company is insolvent and owes him $1,500.

S. B. Echlin, Reo and Cadillac agent in Janesville, Wis., has sold his business to J. A. Strimple, the Mitchell dealer. Strimple will remove from his old location, 16 North River street, and will combine both businesses in the Echlin garage at 219 East Milwaukee street.

Thomas W. Bunnell, who is engaged in the flour and feed business in Toledo, has entered the automobile trade in that city under the style, Bunnell Auto Sales Co., which is located at 3250 Monroe street. Bunnell has the Northwestern Ohio agency for the Cutting car.

The Schacht Motor Car Co. of Boston has been organized to handle the vehicles of that name in and about Boston, Mass. It comprises F. W. Deming, G. A. Buck and A. R. Taintor, who will incorporate the business and will establish a service station on Commonwealth avenue.

Herman B. Stouder of Newton, Ia., has purchased the interests of his partner, Frank Barngrover, in the Auto Specialty Co. and the Non-Leak Balance Valve Co. and has formed a new partnership with Charles Steele. They will continue the business under the style Keystone Garage.

The Moriarity Motor Co., of Kansas City, which is a recent consolidation of E. P. Moriarity & Co. and the Kaw Valley Auto Co., has taken over the Regal branch in that city and will handle the Regal car in Kansas, Oklahoma and Western Missouri. W. R. Wheeler, the former manager of the Regal branch, has been transferred to duty in California.

Recent Losses by Fire.

Los Angeles, Cal.—Lark Motor Car Co., Jefferson and Main streets, garage destroyed. Loss, $12,000.

New York, N. Y.—Mason-Seaman Transportation Co., 626 West 57th street, taxicab garage and office, damaged. Loss, $500.

Detroit, Mich.—Oakland Motor Sales Co., 806-8 Woodward avenue, garage, salesrooms and several cars damaged. Loss, $8,000.

Philadelphia, Pa. — Gregg-William D. Rogers Co., body manufacturers, 1926-34 Arch street, factory damaged. Loss unknown.

REPAIRER'S RESPONSIBILITY FIXED

Court Holds Him Liable for Damages Done in "Trying Out" Car—Owner Wins Hard-Fought Victory.

If an automobile owner leaves his car at a garage to be repaired and if, after the repairs are completed or are in process, an employe of the garage proprietor takes the car out upon the road for a test and inadvertently attempts to climb a tree with the car, the garage proprietor is liable for damages to the vehicle, according to a supreme court ruling handed down last week in Newark, N. J.

In this particular case one Albert G. Brooker was the complainant, and his story was that he bought a car second-hand and then left it with the F. L. C. Martin Automobile Co., of Plainfield, with instructions that it was to be overhauled "from A to Z." What followed was not greatly disputed by either side, it appearing that a mechanic in the garage while testing the car on the road knocked considerable bark off a tree and practically wrecked the car. The mechanic's story was that the accident was caused by a defective steering gear, and the garage proprietor contended that the order for repairs covered the engine only, so he had not investigated the steering gear and had no means of knowing it was defective. He also claimed the road test was an acknowledged part of the repair work, not requiring the car owner's permission.

A lower court gave Brooker a verdict, and in upholding it the supreme court held that, having taken out the car without instruction from the owner, the defendants did so at their own risk and were liable for the consequences. The court said that the prevalence of such a custom was not established with sufficient certainty to constitute a bar to recovery.

Changes Among Prominent Tradesmen.

L. L. Halle has relinquished his connection with the Lovell-McConnell Mfg. Co., of Newark, N. J., makers of Klaxon horns. For a considerable period he represented the company in the eastern part of the United States.

Benjamin A. Rhoads, superintendent of the Dayton Motor Car Co., Dayton O., has been promoted to the post of factory manager. He succeeds J. B. Myers, who resigned to become general superintendent of the Marion Motor Car Co., of Indianapolis.

C. A. Hills has been appointed factory manager of the Abbott Motor Car Co., of Detroit. He gained ripe experience in the Olds and Chalmers establishments, but for the past several years has served as factory manager for the Hupp Motor Car Co.

George Waite, former sales manager of the Simplex Motor Car Co., of Mishawaka, Ind., has been appointed assistant sales manager of the E. R. Thomas Motor Car Co., of Buffalo, N. Y. He succeeds Edward Wells, who resigned to enter the retail trade.

George H. Duck has been appointed manager of the New York branch of the American Locomotive Co., which carries with it supervision of the Alco service department in Long Island City. Previously Duck was manager of the Matheson Automobile Co., of New York.

R. J. Mackenzie, formerly assistant general manager of the Alden Sampson Mfg. Co., of Detroit, has been appointed purchasing agent for the Kelly Motor Truck Co., of Springfield, O. As he served for several years as purchasing agent for the E. R. Thomas Motor Co., of Buffalo, Mackenzie is no stranger to his duties.

H. D. W. MacKaye has been appointed assistant to the president of the Keeton Motor Co.., of Detroit, and will also have charge of the purchasing department. MacKaye's specialty is systematizing and general detail work. It is stated that he has installed or systematized sales departments in several of the largest automobile factories in this country.

Archie D. MacLachlan, sales manager of the Sanford Motor Truck Co., of Syracuse, N. Y., has resigned that office and will return to his home in Cleveland, O., where for several years he was sales manager of the Royal Tourist Co. MacLachlan probably will relinquish identification with the automobile industry, as it is his desire to so locate himself as to avoid necessity for travelling. His successor in the Sanford company has not yet been named.

Additional evidence that the Michigan Buggy Co., of Kalamazoo, purposes becoming more than ever a factor in the automobile industry, which was indicated when W. H. Cameron, former chief engineer of the Willys-Overland Co., was made head of the Michigan engineering staff, is contained in the appointment last week of George H. Daugherty as advertising manager. Daugherty has had wide experience in the advertising agency field, during recent years having been head of Lord & Thomas's copy department in Chicago.

Declares "Steel Blanks" Not "Castings."

The Board of United States General Appraisers has overruled a protest filed by the St. Louis Car Co. against the Collector's assessment on an importation consisting of articles of metal either in the form of steel blanks to be used in the manufacture of beveled gearing for automobiles, or in the form of finished steel parts for magnetos. Duty was collected on the unfinished metal forms at the rate of 35 per cent. ad valorem under paragraph 127 of the Dingley tariff, as "steel forgings," and on the finished metal parts at the rate of 45 per cent. under paragraph 193, as "manufactures of metal not specially provided for." The metal articles were claimed to be properly dutiable as "castings," under paragraph 148 or 149.

APPARATUS THAT ELIMINATES GUESSWORK.

Lack of understanding of the functions and lack of appreciation of the real purpose of scientific instruments commonly has an exaggerating effect in that it tends to surround the apparatus with an air of mystery that acts as a more or less effective bar to better acquaintance. It is in accordance with the dictates of human nature for a man to hesitate to undertake the use of an appliance that, according to his belief, demands the application of knowledge that he does not possess; but it is a fact that in many cases such belief exists without real foundation.

This seems to be the state of affairs that exists with reference to the various appliances that have been devised for making diagrams from the cylinders of gasolene motors. Dynamometers and manographs, for instance, have been, and are, regarded even by many factory men as instruments of such complex construction and requiring such skilled manipulation as to be of value only to the highly educated engineer and scientist for laboratory work. This view of the case is an erroneous one, and undoubtedly is largely responsible for the fact that indicating instruments rarely are used outside of laboratories and factory testing rooms, whereas there is no real reason why they should not be employed in a great many shops where motor repairs and adjustments are made. The extremely practical character of the manograph is indicated by the fact that it will reveal at once, and in an unmistakable manner, faults that otherwise might not even be guessed at. The results of changes in valve setting and other adjustments are made apparent and accurate data on the conditions existing during the working cycle given, not afterward, but while they actually exist. And, finally, the application of the instrument to shop work is in reality a matter of very little difficulty.

While the cost of a good instrument is not unreasonable, even a fairly high price in many cases would be justified by the time saved by its use. Frequently motor faults, apparently baffling, can be detected at once with the aid of an indicator, without even removing the engine from the car, thus saving, perhaps, a tedious and expensive tearing down process. The most refined and scientific methods are employed in the construction of a good motor, and there is no good reason why equally refined methods should not be used in restoring a deranged motor to normal condition, rather than what is called skill or judgment, which but too often really is nothing more nor less than guesswork.

AFFORDING A CLEAR VIEW AHEAD.

Body design and body development have kept pace with the improvement in mechanical structures, but despite the progress, occupants of rear seats of touring cars still are restricted in their outlook, so to speak; their chief view is a rear view of the heads and shoulders of those who occupy the seats in front. Rarely are such views inviting, and few will dare argue that the amount of neck-stretching occasioned by present seating arrangements is wholly desirable or wholly comforting.

Apparently, however, small effort has been made to remedy the state of affairs. Here and there a body has appeared in which the seats have been repositioned but the rearrangement has failed to find favor, or, at any rate, usually has been restricted to a particular brand of cars. The subject, nevertheless, is one that is worthy of serious and more general study. The end to be attained makes it well worth while.

While it scarcely is possible to lower the front seats, a slight elevation of the rear seats and rear flooring is easily possible, and if it can be brought about without giving to the car that outre and high-pitched appearance which characterized the old rear-entrance tonneau it will prove a ready solution of the problem.

On the face of things, and as applied to the average touring car, such an arrangement may be difficult to attain harmoniously, but so far as so-called underslung cars are concerned the elevation of the rear seats and rear flooring affords an immediate and apparently satisfactory answer, and one which there is every reason to believe will add to instead of detract from the appearance of that type of car. It would afford a clear view ahead to the occupants of rear seats, which is a purpose well worth serving and one that scarcely can fail to meet with general appreciation. It, therefore, merits the attention of those most concerned.

The regularity with which the price of gasolene has been advanced since the first of the year strongly suggests the execution of a well arranged program. It will take more than words to convince even a fairly reasonable man that much overworked supply and demand of themselves are responsible for the astonishing increase of 78 per cent. which has been effected in a period of only six months. The situation and the many interests affected suggest that the occasion is opportune for Uncle Sam again to take in hand the probe which he dropped last year on the strength of Standard Oil's promise to "be good."

RUSH TO S. A. E. WATER SESSION

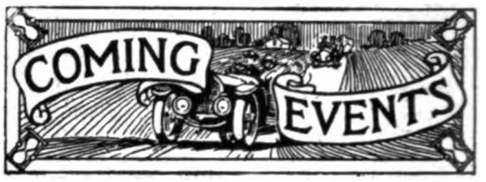
Big Meeting Aboard Boat is Assured—The Program as Finally Arranged—Evening Clothes Are Tabooed.

First announcements to the effect that members of the Society of Automobile Engineers would not require to make reservations on the City of Detroit II, which is the boat that will carry the party on its second annual convention and permit professional sessions to be held in its spacious saloons during the Friday and Saturday, 27th and 28th insts., later proved to be just a little bit premature.

At first it was said that, owing to the fact that the vessel had been chartered for the trip and that no outsiders would be permitted to cross its gangplank on Thursday, there would be no difficulty in accommodating those who had signified their intention of attending the convention. But in making the statement the S. A. E. had reckoned without its host, so to speak, or without its guests, as the case may be. For, according to present indications, the ship will be loaded to her capacity—her human capacity, at least. No less than 360 members have "signed up" for the trip, and as some 80 of them have signified their intention to take wives or daughters, a subsequent and very urgent notification to the effect that it was absolutely essential for comfort to make reservations in advance became necessary.

The convention will be officially opened on Wednesday morning, 26th inst., in the Convention Hall of the Hotel Pontchartrain, in Detroit, the business in hand being a meeting of the Standards Committee. The principal doings will not be inaugurated until 10 o'clock on Thursday morning, however, when the semi-annual meeting will be opened by President H. F. Donaldson with his presidential address. Immediately following, routine business will be in order and will occupy the time until noon. when a recess for luncheon will be moved. At 1 o'clock atuomobiles will be provided, and the day will be rounded out by visits to some of the larger factories for which Detroit is famous. In the evening the members and the ladies of the party will go aboard the City of Detroit II at the D. & C. dock at the foot of Wayne street. Lines will be cast off promptly at 8 p. m., and the sail to Mackinac Island along one of the most wonderfully scenic routes in the Great Lakes will be commenced.

On Friday morning and afternoon and Saturday morning professional sessions will occupy the time of the S. A. E. members, the following long list of papers and reports being scheduled for discussion:



The Standardization Work of the Society of Automobile Engineers, by Henry Souther, Chairman of the Standards Committee; Report of Data Sheet Division, by Cecil P. Poole; Nomenclature Division, by Howard E. Coffin; Cost of Work with Gasolene Motor Trucks, by Louis Ruprecht; Motor Sizes and Drive Ratios for Commercial Vehicles, by E. P. Batzell; Fourth Report of Wheel Dimensions and Fastenings for Tires Division, by Wm. P. Kennedy; Report of Truck Standards Division, by Wm. P. Kennedy; The Effect of Relation of Bore and Stroke in Automobile Engines, by J. Wilkinson; A Comprehensive Motor Test, by Herbert Chase (introduction by Professor F. R. Hutton); Standardization and Co-operation in Motor Testing, by Herbert L. Connell; Third Report of Broaches Division, by C. W. Spicer; Fourth Report of Ball and Roller Bearings Division, by David Ferguson; Third Report of Frame Sections Division, by J. G. Perrin; Worm Gears, by Frank Burgess; Stability of Automobile Propeller Shafts, by J. M. Thomas; Method of Brake Capacity Determination, by S. I. Fekete; Fourth Report of Carburetter Fittings Division, by G. G. Behn; Leaf Springs, by L. J. Lane; Third Report of Springs Division, by Harold L. Pope; Third Report of Miscellaneous Division, (a) Rod and Yoke Ends, (b) General Flange Construction, by A. L. Riker; Third Report of Sheet Metals Division, by T. V. Buckwalter.

In addition to the foregoing list of papers, the following list of subjects has been suggested for discussion, provided time permits; Relative Merits of American and European Carburetters; Electrical Wiring and Gasolene Connections on Motor Cars; Rear Axle Transmission in Motor Cars; Motor Car Acceleration; Gas Engine Inlet and Exhaust Manifolds.

The return to Detroit will be made on Saturday evening, the ship being scheduled to dock at 10 p. m. It is suggested that those of the members who contemplate leaving Detroit on Saturday night make railroad reservations in advance, for the reason that the present time of the year is particularly productive of well-filled trains.

The efforts of the organizing committees to make the summer meeting as much an outing as possible—a sort of picnic where acquaintances can be ripened—is plainly apparent in the preparations which have been made for entertainment on the boat and during the short stay at Mackinac Island. As a further precaution against the serious side obtruding itself too much, it is announced that all gatherings on the steamer will be of a strictly informal nature. Members are warned not to encumber themselves with such evidences of precivilization as evening dress, and it is suggested that a cap, a light raincoat and a pair of rubber-soled shoes will be found very much more useful.

The Minnehaha County Automobile Club has been reorganized at Sioux Falls, S. D. H. T. Brownell is the new president, while A. J. Keith and F. H. Hollister are secretary and treasurer, respectively.

June 27-28, Chicago, Ill.—Interclub reliability run of the Chicago Automobile Club and the Chicago Athletic Association.

June 27-29, Detroit, Mich.—Midsummer meeting of the Society of Automobile Engineers.

June 28-29, Laurel, Md.—Track races promoted by R. E. Shadel.

June 29, Narbeth, Pa.—Track races under the auspices of the Belmont Motor Club.

July 4, Wildwood, N. J.—Straightaway races, under the auspices of the North Wildwood Auto Club.

July 4-5, Butte, Mont.—Track races under the auspices of the Butte Motor Club.

July 4-5, Tayor, Tex.—Track races under the auspices of the Taylor Automobile Club.

July 4-6, Old Orchard, Me.—Beach races under the auspices of the Old Orchard Automobile Association.

July 5-6, Tacoma, Wash.—Road races under the auspices of the Montamara Festo Automobile Commission.

July 7, Fort Wayne, Ind.—Track races promoted by E. A. Moross.

July 13, Forestville, N. Y.—Hill climb under the auspices of the Forestville Motor Club.

July 15-20, Milwaukee, Wis.—Reliability tour, under the auspices of the Wisconsin State Automobile Association.

July 15-16, Cleveland, Ohio—Reliability run under the auspices of the Cleveland News.

July 21, St. Louis, Mo.—Track races under the auspices of the Universal Exposition Co.

July 22, Dallas, Texas—Farm and Ranch Tour under the auspices of the Dallas Automobile Club.

August 8-10, Galveston, Tex.—Beach races under the auspices of the Galveston Automobile Club.

August 23-24, Elgin, Ill.—Chicago Motor Club's national stock chassis road races.

September 2-3, Indianapolis, Ind.—Races on the Motor Speedway, promoted by the Indianapolis Motor Speedway Co.

September 7, Hadine, Minn.—Track races promoted by the Minnesota State Fair Association.

September 17, Milwaukee, Wis.—Grand Prize road race under the auspices of the Milwaukee Automobile Dealers' Association.

September 21, Milwaukee, Wis.—Vanderbilt Cup race on the Greenfield course, under the auspices of the Milwaukee Automobile Dealers' Association.

BRUCE-BROWN STARTLES FRANCE

With Revived Grand Prix Within His Grasp, a Leaky Fuel Tank Undoes Him —Boillot Takes the Honors.

After permitting it to lie dormant for four years, the Automobile Club of France revived the Grand Prix race on Tuesday and Wednesday last, 25th and 26th inst., and cable reports state that the revival was auspiciously performed in the presence of a huge crowd that lined the Deippe circuit. Despite the fact, the French race, which went for 956 miles, now lacks the world-interest it once possessed.

In America the chief interest in the revived classic, which was run in two sections, centered in the performance of David Bruce-Brown and Ralph De Palma, who, although they piloted Fiat cars of Italian manufacture, are Americans to the manor born. The one American car which was to have competed, a Ford, driven by a Frenchman, H. De Passe, did not start.

Although both American drivers finally were disqualified for technicalities, it was Bruce-Brown who set the pace throughout three-quarters of the distance, and had not his fuel given out at an inopportune time it is not at all unlikely the first honors would have been his portion.

Throughout the first day's flight of 478 miles, Bruce-Brown gave his foreign competitors a run for their money. After assuming the lead in the very first round of the 47.8-mile circuit, he never was passed, and finished the ten laps which completed the first day's program in 6:36:38, at an average rate of 72.4 miles an hour. George Boillot, who piolted a Peugeot, took second position, crossing the tape a little over two minutes later. Louis Wagner, who also drive a Fiat machine, ended the first day in third position, his time for the distance being 7:12. The American driver made the record for a single circuit for the first day when he rounded the course in 37:18⅕, at nearly 76.8 miles an hour.

But one accident of a serious nature marred the sport of the first day; it proved fatal to Bessagnana, a mechanician on the Gregoire car, which was piloted by Collinet and which came to grief in the second lap. Collinet attempted to pass Garcet in a Calthorpe on one of the turns, but misjudged his distance and the French and English machines locked wheels. The Gregoire car turned completely over and both driver and mechanician were pinned beneath it, the former being seriously injured and the latter instantly killed.

For the first three laps on the second day Bruce-Brown continued the role of pacemaker, with Boillet and Wagner following in the order named. Unfortunately, however, his fuel tank sprung a leak, and the waning supply of gasolene caused motor trouble which cost Bruce-Brown his position before the fourth lap had been completed. When half way around the circuit on the fifth lap, fuel failed him completely, which necessitated a stop.

All would have been well, had the machine stopped at no great distance from the pits, but such was not the case. Unable to push the heavy car to the pits, he replenished the fuel supply at a neighboring roadhouse and was, as a consequence, disqualified. He received the red flag, which told him he was out of the running, when he passed the judges' stand for the fifth time, but only stopped long enough to enter a formal protest. He finished the race, unofficially in third position, Boillet having profited by the delays of the former pacemaker and finished in 7:34 20, his total time for the two days being 14:11. Wagner, too, drove his Fiat car across the tape ahead of Bruce-Brown and finished three minutes later than the winner. Rigal, driving a British built Sunbeam car in the light car class, officially finished third, his time being 14:38:36.

De Palma also was disqualified for filling up his fuel tank at a place remote from the pits, but as he was at no time a dangerous factor in the race, his misfortune affected him little, if at all.

Indianapolis Abandons Labor Day Meet.

Because of failure to obtain assurances of a sufficient number of really attractive entrants to make the holding of a fall meet worth while, the management of the Indianapolis Speedway has abandoned its plan for a two days' meet to be run Saturday, August 31st, and Labor Day, Monday, September 2nd, for which sanction already had been granted by the Contest Board of the A. A. A. It is now proposed that another day be added to the May program, which then will comprise the single 500-mile sweepstakes event and a series of short contests in which the contenders will compete for such prizes and trophies as the Remy Brassard and trophy and the Wheeler-Schebler trophy, and, of course, for the parcels of cash which are more attractive than trophies to the general run of professional drivers.

Whether or no the abandonment of the Labor Day card at Indianapolis will in any way affect the dates on which the Vanderbilt and Grand Prize races are scheduled to be run is a matter of conjecture, but in view of the fact that considerable but unavailing persuasion was offered by the managers of the Milwaukee races in an endeavor to have the Speedway card dates changed, it seems not at all unlikely that a shift in the Milwaukee schedule may come to pass.

Club Organized in Devil's Lake.

The Devil's Lake Automobile Club has been formed in the North Dakota town of that name with these officers: President, Dr. G. J. McIntosh; vice-president, George W. Moore; secretary, Thomas Turner; treasurer, George Chaffee.

KULICK HONOR MAN AT ALGONQUIN

Proves "Whole Thing" on the Twin Hills— Rain Interrupts but Benefits Diminished Glory of Event.

For the seventh time the twin hills at Algonquin, Ill., supplied the setting for the annual hill climbing contest of the Chicago Motor Club which, owing to the untimely intervention of Jupiter Pluvius, was not completely decided until Friday last, 21st inst., although the major portion of the program was run on the day previous, according to schedule. Frank Kulick, who drove a specially built Ford, which was almost as light as a figurative feather, although powered with a motor with a piston displacement of 410 cubic inches, not only annexed the Algonquin cup, which has been the property of "Eddie" Hearne since the hill climb of 1911, but also lowered the records made by that Benz driver both for the combined time made on the two hills, and for the separate performances. Kulick's time for the Algonquin hill, which is the shorter, albeit steeper, of the pair, was 15⅗ seconds, which is 1⅕ seconds better than the time made by Hearne; the Ford driver mounted Phillips hill in 27⅕ seconds, which is 3⅗ seconds better than the time of the former cup holder.

Kulick, who made such a good showing in the event last year when he was the runner-up to Hearne, had things his own way in every event in which he contested save one. He won the Class C, 301-450 inches, the Class E, under 600 inches, and the free-for-all events, his time for each event in the order named being 43⅘ ,42⅗ and 44⅕ seconds; he lost the Class C, 161-230 inches event by only two-fifths of a second. Dusenberg in a Mason took second place both in the Class E and the free-for-all event, his time being 48 seconds in each case. C. Anderson ran his Stutz into second place in the Class C, 301-450 inches event, but he was 8⅕ seconds behind Kulick.

Not alone were the entries fewer than last year, which in itself would tend to detract from the contest, but the program which last year comprised 18 separate events was shortened to seven, and of these but one was for stock cars. Also the many professional stors who last year completed in the Indianapolis Speedway event and who then journeyed to Algonquin, were absent. But two of the contenders, Joseph Nikrent and Kulick, were known to fame. In shortening the program the class wherein the cars are graded according to selling price was cut to one event, and this single stock car event was run with but a single entrant, A. Monsen, who piloted a Bergdoll car up both inclines in a total of 90⅘ seconds. In the Class C, under 160 inches displacement event, W. G. Wordingham, who drove a Herreshoff, his total time being

Digitized by Google

1:26⅗, also ran " by his lonesome" and won a hollow victory.

The Class C, 161-230 inches event was hotly contested by G. Shillo in a Mercer and Dusenberg in a Mason, both of whom mounted the hills in a total of 49 seconds, with Kulick but ⅗ of a second behind them. Joe Nikrent, who drove a Case car, captured first place in the 231-300 inches class, his total time being 50⅗ seconds.

The downpour of rain which interrupted the proceedings on Thursday before the contenders in the Class E, under 600 inches displacement event, and the free-for-all had had time to climb the longer gradient, although for the time being it converted the erstwhile race course into a veritable river, really improved the condition of the road, so that the events run on Friday were contested under ideal conditions.

The very original mode of procedure which always has been carried in the running of the Algonquin hill climb was again adhered to, and each of the events was run on the Algonquin hill on Thursday morning and rerun on the longer hill on Thursday afternoon or Friday morning. The times made on both hills were added together, as usual, to give the total time. The summary:

Class A, Division 3A, $1,201-$1,600.

Driver and Car.	Algonquin.	Phillips.	Total.
A. Monson, Bergdoll	0:43	0:47⅘	1:30⅘

Class C, Division 1C, under 160 inches.

W. G. Wordingham, Herreshoff	0:38⅘	0:47⅘	1:26⅗

Class C. Division 2C, 161-230 inches.

A. G. Schillo, Mercer	0:18	0:31	0:49
Dusenberg, Mason	0:18	0:31	0:49
F. Kulick, Ford	0:17⅗	0:31⅘	0:49⅗

Class C. Division 3C, 231-300 inches.

Joe Nikrent, Case	0:20	0:30⅗	0:50⅗
H. W. Ogren, Colby	0:25⅘	0:40⅘	1:06⅗

Class C. Division 4C, 301-450 inches.

F. Kulick, Ford	0:15⅗	0:28⅕	0:43⅘
C. Anderson, Stutz	0:21	0:32	0:53
M. Moore, Stutz	0:21⅘	0:32	0:53⅘

Class E, under 600 inches.

F. Kulick, Ford	0:15⅗	0:27⅕	0:42⅗
Dusenberg, Mason	0:18⅕	0:29⅘	0:48
Joe Nikrent, Case	0:18⅕	0:30⅕	0:48⅗
H. W. Ogren, Colby	0:24⅗	0:41⅗	1:06

Class D, Free-for-all.

F. Kulick, Ford	0:15⅘	0:28⅗	0:44⅕
Dusenberg, Mason	0:18	0:30	0:48
A. G. Schillo, Mercer	0:18⅗	0:31	0:49⅗
C. Anderson, Stutz	0:22⅕	0:35⅕	0:57⅗
H. W. Ogren, Colby	0:28⅘	(Did not finish)	

Seek "Automobile" Street in 'Frisco.

Because of the congestion of traffic in Sutter street, San Francisco, practically now the only available thoroughfare for automobile traffic between the city and the Western Addition, the automobile associations of that city have asked the municipal authorities to repair Post street and set it aside as an exclusive auomobile thoroughfare, at least during rush hours. Post street has but a short stretch of street car tracks, and with the addition of a few blocks of new pavement would make a good driveway for the automobiles. Many business men who live in the Western Addition would appreciate some means of reaching their places of business without the delay and danger incident to the congestion of mixed traffic which at present prevails.

MENENGHETTI GETS "MEAL TICKET"

Italian "Unknown" Finally Takes Remy Brassard from Burman at Akron Meet—Four Events Constitute Program.

If Louis Menenghetti, the Italian "unknown," had not wrested the Remy Brassard or $50 per week "meal ticket" from Robert Burman, there would be little to say of the four-event racemeet which, promoted by E. A. Moross, was run on the Fountain Park track at Akron, Ohio, on Saturday last, 22d inst. Just how Burman came to relax his grip on the "meal ticket" which he had held so firmly in his grasp since May of last year is not quite clear, but it happened, nevertheless. The race was run in three heats of three miles each, and although the Italian won the first two, the third heat also was run apparently to give the crowd its money's worth. Menenghetti won it also, his times being 4:47⅕, 3:44⅗ and 3:09, respectively.

A two-mile Class C event, for cars in the 161-250 inches division, was won by W. L. Stauffer in a Flanders, in 3:23, an exhibition mile driven by Burman in the Blitzen Benz in 1:14⅕, and a five mile free-for-all which was taken by John Raimey, who drove an Ohio car, in 8:15 completed the program. The summary:

Two miles, for cars of 161-250 inches displacement—Won by W. L. Stauffer (Flanders); second, James Jones (Hupmobile). Time, 3:23⅕.

Three miles, free-for-all. First heat for Remy Brassard and trophy—Won by Louis Menenghetti (Mercedes); second, Robert Burman (Ohio); third, E. A. McDonald (Benz). Time, 4:47⅕. Second heat—Won by Louis Menenghetti (Mercedes); second, Robert Burman (Ohio); third, E. A. McDonald (Benz). Time, 3:44⅗. Final heat—Won by Louis Menenghetti (Mercedes); second, Robert Burman (Ohio); third, E. A. McDonald (Benz). Time, 3:09.

One mile, time trial—Robert Burman (Benz). Time, 1:14⅕ from a flying start.

Five miles, free-for-all—Won by John Raimey (Ohio); second, W. L. Stauffer (Flanders). Time, 8:15.

Itinerary of Four States Tour Revised.

Evidently the addition of a second "day of rest," so that none of the entrants in the Four States Tour will become unduly fatigued, was considered advisable by the Board of Directors of the Indiana Automobile Manufacturers' Association, for the itinerary has so been altered that on July 21st, instead of journeying from Huntington, W. Va., to Maysville, Ky., as was announced in the itinerary as originally drawn, the tourists will rest in Huntington. Other slight changes have been made in the route, 1,283 miles in extent, which will be covered between July 9th and the 24th, as well as in the time schedule. On July 18th, instead of resting at Washington Court House, Ohio, the cavalcade will stop at Chillicothe and will not reach Washington Court House until noon of the following day. This and the addition of July 21 to supplement the 13th as a day of no travel, however, are the chief changes.

The itinerary in revised form is as follows: July 9, Indianapolis, Kokomo, Peru (noon), Wabash, Huntington and Fort Wayne. July 11, Lima, Findlay, Fostoria, Fremont (noon) and Tiffin. July 11th, Tiffin, Bucyrus, Mansfield (noon), Ashland, Barberton and Akron. July 13th, tourists rest at Akron. July 14th, Akron to Canton. July 15th, Canton, Massillon, Canal Dover, New Philadelphia, Cadiz (noon), and Wheeling, W. Va. July 16th, Wheeling, Cambridge, O. (noon), New Concord and Zanesville. July 17th, Zanesville, Newark and Columbus. July 18th, Columbus, Lancaster, Circleville and Chillicothe. July 19th, Chillicothe, Waverley and Portsmouth. July 20th, Portsmouth, Ironton, Coal Grove, Ashland, Ky., Charlottesburg, Kenova, W. Va., and Huntington, W. Va. July 21st, tourists rest at Huntington. July 22nd, tourists take boat to Maysville, Ky., from Huntington at 3 A. M., Maysville (noon), Paris and Lexington. July 23rd, Lexington, Frankfort, Shelbyville and Louisville. July 24th, Louisville, New Albany, Scottsburg, Seymour, Columbus (noon), Franklin and Indianapolis.

Four Clean Scores in Pine Tree Contest.

Of the nine contenders who started in the Pine Tree Reliability Tour, which started from Portland, Me., on Thursday last, June 20, under the auspices of the Pine Tree Motor Contest Association, and covered a more or less tortuous circuit, 350 odd miles in extent, which led from Maine into New Hampshire and back again, but four finished with a clean slate. They were L. C. Gilson, who drove a Mitchell; J. L. Judd, who piloted one of the two Jackson cars which were entered; E. W. Blanchard, in a Stoddard-Dayton, and N. E. Haskell, who piloted a Stearns-Knight.

Penalties began to pile up on the very first day of the three-day run, and before the 80 miles to Gorham, N. H., the night stop, had been covered, the R. C. H. car, which was guided by Fred Morse, had annexed 31 points, all occasioned by the occasional overheating of the motor, owing to the waste of water caused by a leaky radiator, while the Oakland entry which L. A. Stoughton drove and which had skidded into a ditch with a demolished wheel as a result, was penalized 280 points. On the 166 mile run to Bangor two contenders, O. S. Morris in a Jackson and George Merrow, who drove the American, were penalized 11 points each. On the third day's run, 110 miles, from Bangor to the starting point, Merrow's American received 82 points, and the Ford car, which was driven by A. M. Spear, received two points, all through troubles having their origin in the motor.

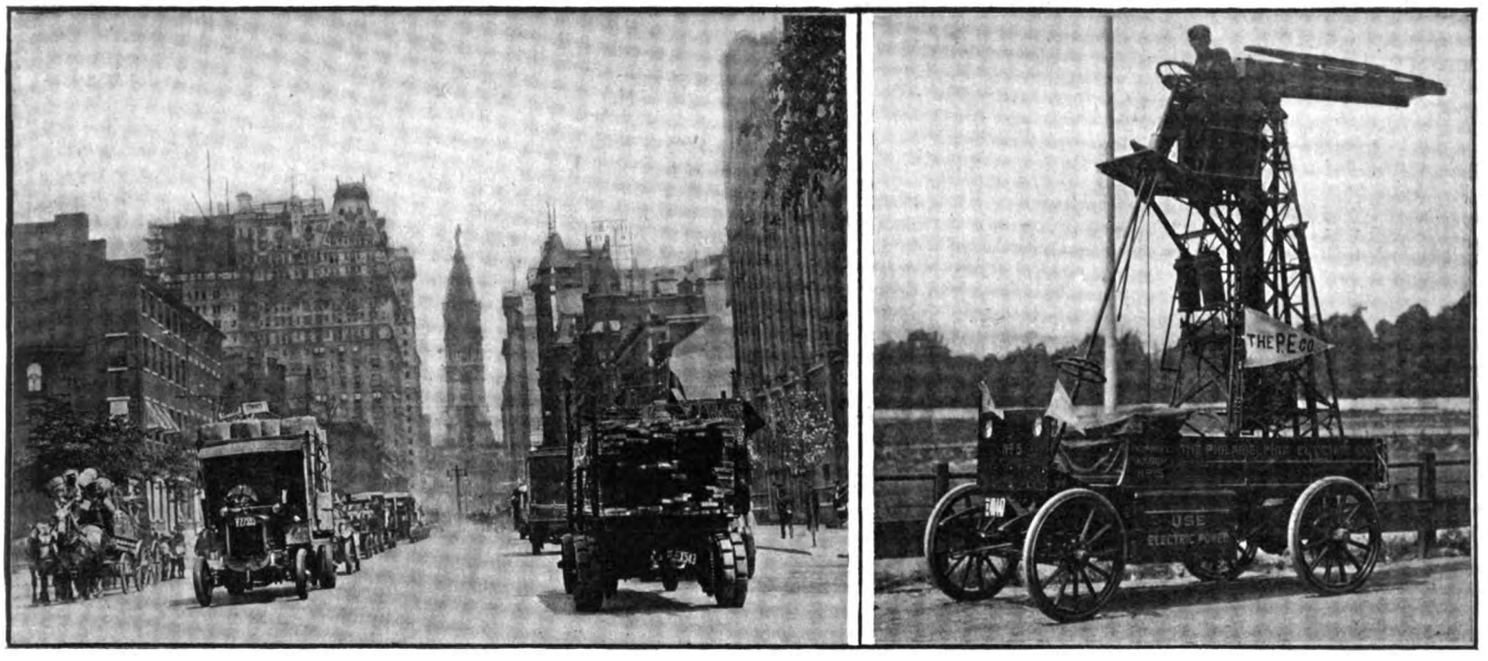
TRUCKS PARADE IN QUAKER CITY



Half-Thousand Vehicles, in Five Divisions, Arranged in Uncommon but Logical Order—Some Picturesque Types.

There are motor truck parades and motor truck parades, and each is conducted with the avowed purpose of letting the prospective purchaser get a glimpse of the type of vehicle in which he is most interested while "in action"—that is, while operating under service conditions. According to the usual order of things, the line-up of the vehicles is made with scant regard either as to size, purpose or type of the vehicles, and trucks of the heaviest type are oftentimes preceded or followed, as the case may be, by the lightest type of delivery wagon, and the electric vehicles are mixed indiscriminately with the gasolene propelled machines.

It was different with the parade promoted by the Philadelphia Enquirer, which on Thursday last, 20th inst., wound its way slowly through all of the principal business streets of Philadelphia and proceeded finally up Belmont avenue as far as Belmont Park, where a great number were parked throughout the afternoon, in order to afford opportunity for closer inspection. The vehicles were divided into five groups, and each group was distinguishable by pennants and decorations of a different color from the rest. The first four groups embraced gasolene machines exclusively. In the first section, wherein the vehicles were decorated with red flags, no vehicle of a carrying capacity of less than 3½ tons was permitted; in the second section the carrying capacities were between 2 and 3½ tons and the trucks carried blue markers. The third and fourth divisions, which were recognizable by the orange and green pennants, respectively, embraced trucks with capacities up to one ton. The last division was for electric vehicles exclusively, and all sizes of vehicles were grouped. A marshall supervised the arrangement of the vehicles in each division and each section was preceded by a band wagon.

Variety naturally was to be expected with so large a caravan, which embraced some 509 vehicles of 71 different makes, and each of the five divisions yielded besides a great number of vehicles of orthodox design, several which, owing to unusual construction or adaptation, created more than an ordinary amount of interest. Quite a little attention was stirred up by the appearance in the first division of the Alco truck which is to cross from coast to coast laden with soap, while a Saurer truck, which carried a horse as a passenger and bore signs with the single word "Emancipation" interested not a few of the observers who lined the sidewalks three deep.

The "features" of the second division were diverse, and included besides the large service truck of the Bell Telephone Co., which was exhibited with a complete complement of pole setting appurtenances, including a reel of lead-covered cable which was towed behind, a combination hearse and funeral carriage designed to carry not only the casket but the mourners up to two dozen in number, as well, and which was entered by the Lawncroft Cemetery Association. In contradistinction to the Saurer machine which carried the horse in the first division, a White 2-ton truck bore a finished chassis of a White pleasure car. The third division, which might be termed the "Autocar" division, because of the number of cars of that make which were entered in it, included the Autocar truck which recently underwent the army test and which was decorated with numerous photographs depicting incidents which occurred during the tests, several picturesque "water wagons" and a police patrol with full complement of bluecoats, which was entered by the General Motors Co. The operation of these "water wagons," which is conducted by the Women's Pennsylvania S. P. C. A., is purely a Philadelphia institution. The trucks, which are painted white and are provided with a large tank for carrying water, which is used to allay the thirst of the equine species, and a water cooler in which ice water is provided to fill the needs of the drivers, were presented to the society as memorials by the friends and relatives of members who have joined the silent majority.

THE PARADE ON MARKET STREET AND ONE OF THE PICTURESQUE VEHICLES IN LINE

The fourth division, which was composed of delivery vehicles, was, as naturally was to be expected, by far the longest division of the five.

The electric division included everything from a light delivery runabout to the 3-ton trucks which were entered by the Philadelphia Electric Co. Especial interest attaches to the factory truck which was exhibited by the Woods Electric Garage and which, although propelled by a motor of only 2 horsepower capacity, through the intermediary of road wheels less than a foot in diameter, and guided by a "chauffeur" who stood on the rear platform and steered by means of a tiller, made the complete trip to the park and back without mishap. The "dog catchers' wagon" of the S. P. C. A. also was in evidence in the electric division.

Music in plenty was supplied for the entertainment of the vehicle drivers and the occupants of the trucks as well as the observers, and the music was well distributed so that all might share in the enjoyment;

Digitized by Google

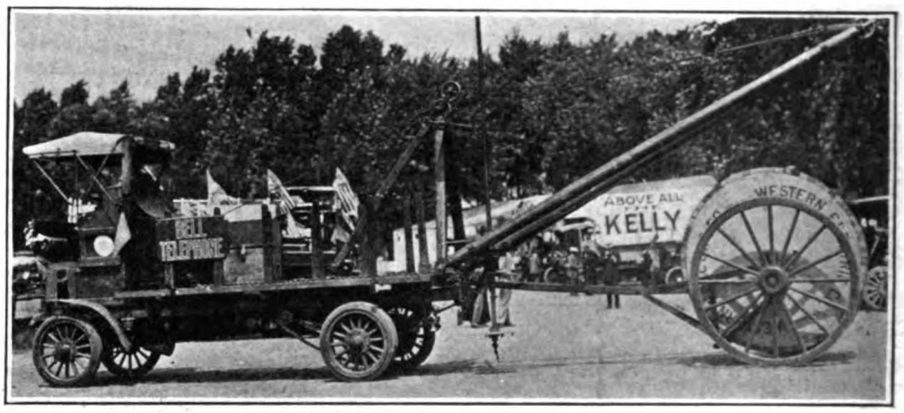
large trucks were pressed into service as band wagons and one preceded each section of the parade, and, lest those who brought up the rear of the electric division grow weary, a sixth band made music at that point.

The following is a list of the separate makes of cars in the parade, listed according to their numerical strength: Autocar, 79; Packard, 47; Mack, 38; Commercial, 29; White, 29; G. M. C., 21; Gramm, 19; Ford, 18; Garford, 17; Alco, 16; Wilcox, 16; Hart Kraft, 10; Cartercar, 9; Kelly, 9; General Vehicle, 8; Chase, 7; Durable Dayton, 7; Peerless, 7; Studebaker, 7; Detroit Electric, 6; Kissel Kar, 6; Little Giant, 6; Service, 6; Buick, 5; Pierce-Arrow, 5; Saurer, 5; Columbus Electric, 4; Dart, 4; Decatur, 4; Atterbury, 3; Cadillac, 3; Courtland, 3; Mais, 3; Mitchell, 3; Walker, 3; Waverley, 3; Woolston, 3; Croxton, 2; Grabowsky, 2; Hatfield, 2; Kendle, 2; Martin, 2; Rowe, 2; Stanley Steamer, 1; Automatic, Baker Bell, Baker Electric, B. O. E., Commer, Dennison, Franklin, Flanders, Hupp Yeats, Knox, Lansden, Lincoln, Maxim Tricar, Maxwell, Metz, Morgan, Otto, Philadelphia Electric, Pope Hartford, Premier, Sampson, Sandusky, Seitz, Sharon, Stoddard-Dayton, Thomas, Warren, 1 each.

PHILADELPHIA "WATER-WAGON"

Truck Club to Offer Police Medal.

Emulating the example of the Automobile Club of America, and as an evidence of its appreciation of the work of the traffic police, the New York Motor Truck Club has voted to present annually a gold medal to the policeman who, in the course of a year, proves himself to be most efficient as a handler of traffic. The club has appointed a committee to draft the conditions of award and other details, but thus far little has been decided except that the presentation will be made at the annual police inspection.



Rockford Club Chooses New Officers.

Dr. A. B. Atchison was elected president of the Rockford (Ill.) Automobile Club at the annual meeting. The other offices were filled as follows: Vice-president, C. R. Osborn; secretary, Frank M. Bertrand; treasurer, E. A. Anderson. The executive committee comprises: A. T. Roberts, Dell McPherson, W. W. Sawyer, Fred K. Carrico, E. L. Thayer.

MOROSS'S MEN VISIT YOUNGSTOWN

Menenghetti "Repeats" in Brassard Race and Raimey Bags a Block of Four—Unprofitable Day for Burman.

Probably the most interesting of the eight events which were run on Sunday last, 23d inst., by E. A. Moross and his stable of stars and near-stars for the benefit of the Youngstown (Ohio) public, were the three three-mile free-for-all events which were run as heats for the Remy Brassard and trophy, two of which were won by Louis Menenghetti, the Italian "Unknown" who piloted a Mercedes car first across the tape in both the first and in the final heats, and who first got a grip on the "meal ticket" the day before at Akron. Menenghetti's time was 3:31 and 3:36, respectively, while the best Burman, who in a Benz won the second heat, could do was 3:44.

ANOTHER PICTURESQUE EXHIBIT—A POLE-ERECTING VEHICLE

Burman landed in second place in the first heat, in which he drove the Cutting machine, and in the last heat, in which he drove the Benz, while the other contestant, E. A. McDonald, who piloted the Benz in the first and the Cutting in the second and third, came third in each of the three events. McDonald and Burman changed mounts after the first heat. Had either Burman or McDonald won the majority of the events, they must have waived any claims for either money or trophy, for according to the deed of gift under which the Remy Brassard is competed for, it cannot change hands more than once every ten days; and Menenghetti had won the trophy only the day before.

John Raimey, who drove an Ohio, also was a star performer. He won each of the four events in which he entered, including two Class E, free-for-alls, one for five and the other for 25 miles, which he completed in 5:30 and 34:16½, respectively, a Class C, 301-450 inches event, which went for five miles and which he completed in 5:53, and the final event of the day, a five-mile free-for-all handicap, in which he started from scratch against three other contenders, each of whom had a time allowance and finished in 5:24½. Burman drove a single exhibition mile in the Blitzen Benz in 1:08½. The light car event, five miles for cars in the 161-250 inches displacement class, went to a local driver, C. Lucas, who covered the distance in 5:46 in a Firestone-Columbus. The summary:

Five miles, for cars of 161-250 inches displacement—Won by C. Lucas (Firestone-Columbus); second, W. L. Stauffer (Flanders); third, G. Faulkinson (Ford). Time, 5:46.

Five miles, for cars of 301-450 inches displacement—Won by John Raimey (Ohio); second, Albert Elton (Cadillac); third, George Seidner (Warren). Time, 5:53.

Five miles, Class E, for cars under 600 inches displacement—Won by John Raimey (Ohio); second, Robert Burman (Cutting); third, Albert Elting (Cadillac); fourth, George Seidner (Warren). Time, 5:30.

Three miles, free-for-all, for Remy Brassard and trophy—First heat—Won by Louis Menenghetti (Mercedes); second, Robert Burman (Cutting); third, E. A. McDonald (Benz). Time, 3:31. Second heat—Won by Robert Burman (Benz); second, Louis Menenghettti (Mercedes); third, E. A. McDonald (Cutting). Time, 3:44. Final heat—Won by Louis Menenghetti (Mercedes); second, Robert Burman (Benz); third, E. A. McDonald (Cutting). Time, 3:36.

One mile, time trial—Robert Burman (Benz). Time, 1:08½ from a flying start.

Twenty-five miles, Class E, for cars under 600 inches displacement—Won by John Raimey (Ohio); second, Albert Elton (Cadillac); third, W. L. Stauffer (Flanders). Time, 34:16½.

Five miles, free-for-all handicap—Won by John Raimey (Ohio) from scratch; second, Albert Elton (Cadillac), 35 seconds handicap; third, George Seidner (Warren), 40 seconds handicap. Time, 5:24½.

Bowen Heads Owensboro Club.

At the annual election of the Owensboro (Ky.) Automobile Club, R. W. Bowen was chosen as president. The other officers of the organization are: Vice-president, Dr. O. W. Walsh; secretary, H. L. Scharlich; treasurer, W. L. Reno.

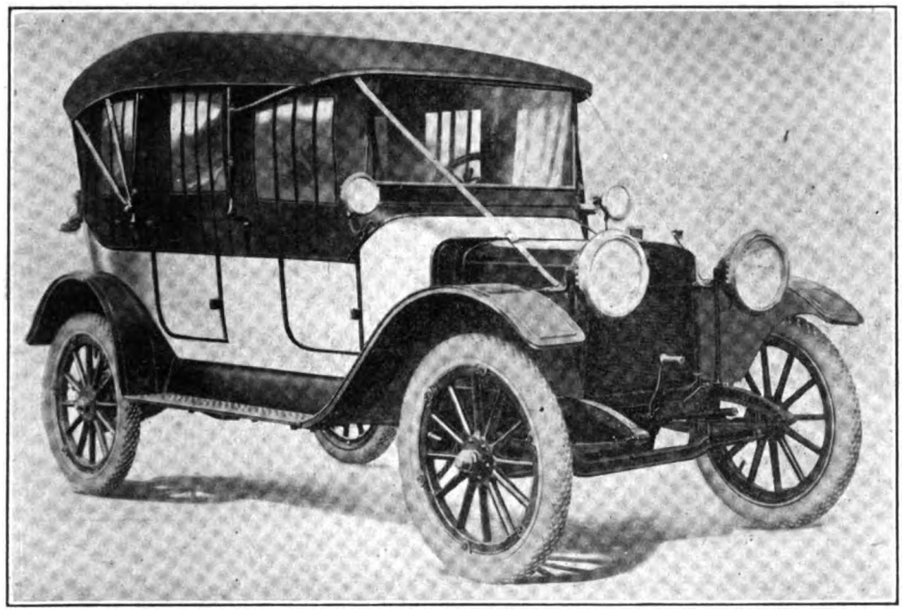
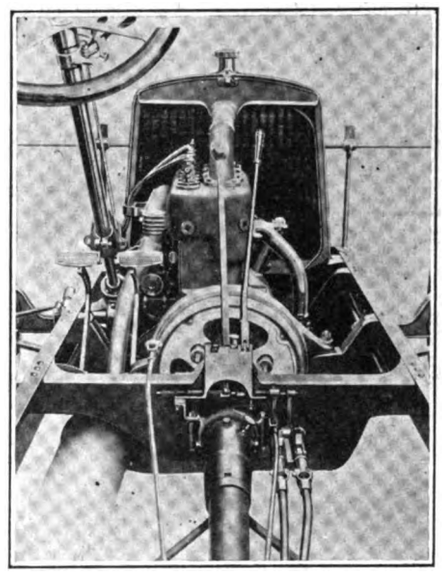
NEW R. C. H. "BEST" NOT "BETTER"

Makers Explain Application of Adjectives to Latest Product—Equipment Changes Principal Alterations in Line.



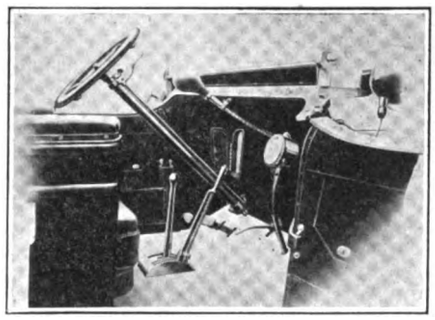
By way of carefully eradicating any possible misconception that might have been engendered by the R. C. H. Corporation's somewhat unusual statement to the effect that the latest edition R. C. H. car, which just has made its appearance, "is not a better car," it is explained almost in the same breath that it is impossible to apply the comparative degree of the adjective good to a product that from the first has been apostrophized by the superlative degree of the same adjective. Which is to say, there has been found no room for improvement, and the revised R. C. H. car, which, in view of the factory policy of the manufacturer, quite naturally follows the model that early last Fall made its initial appearance, is really so little revised in the usual sense of the word as to be practically unchanged.

Such changes as have been made concern neither the design nor the construction of individual parts, but are rather in the form of additions to equipment, which makes plain the fact that though there may not have been the possibility actually to better the mechanical construction of the car, the manufacturer has not hesitated to better the value of the investment represented by the purchase price. Practically the only change in construction which has been made embraces the addition of hand emergency brake lever, which takes the place of the ratchet pedal heretofore employed. Additions to the equipment which in a measure account for an increase of $50 in the price of the five-passenger touring car, which now lists at $900, include electric lights throughout, demountable rims with an extra rim and holders, Warner speedometer, "Jiffy" side curtains, rear view mirror and a "Tally-ho" horn. Standard equipment which last year was featured is included as a matter of course and embraces a top with boot, folding windshield, jack, tire pump and repair kit and the usual complement of tools and spare parts.



Bespeaking the maximum of simplicity tempered with accessibility, the motor remains without change, the four cylinders being cast in a single block with the intake, exhaust and water passages cored in. The distinctive construction with the magneto and the carburetter totally divorced on opposite sides of the engine, a practice which at the time of its adoption was explained as eliminating the possibility of fires resulting from stray sparks igniting gasolene fumes, while at the same time permitting the gas to be heated prior to its inspiration, is retained. The carburetter is of the float-feed single jet type and has but two points of adjustment. The cylinders measure 3¼ inches bore and 5 inches stroke, and under the Royal Automobile Club of Great Britain formula, which, it is explained, has been used in preference to the S. A. E. formula in obtaining the nominal rating, for the reason that the latter formula does not take into consideration power increase due to lengthened stroke, the indicated horsepower is 25. Under bench tests, however, 27 horsepower has been realized at 1,700 revolutions a minute.

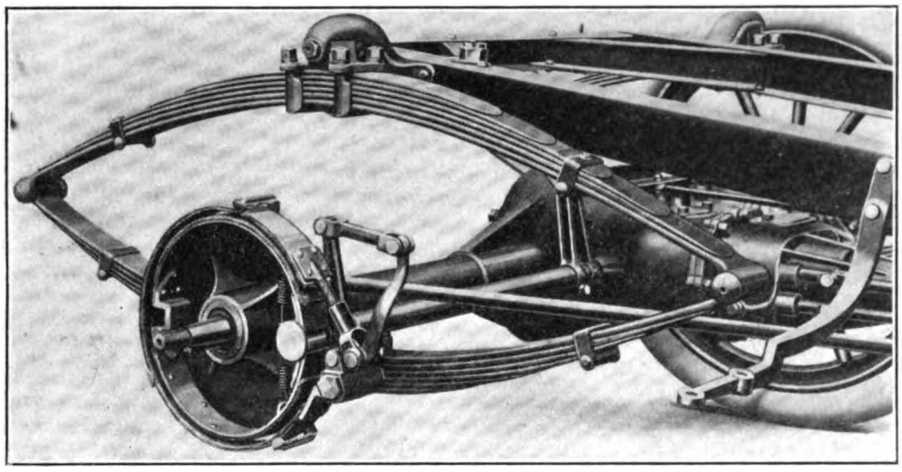
As heretofore, lubrication is effected entirely by splash, experience having proven that under normal running conditions the amount of oil fed up hill and down dale varies as the speed of the engine and maintains all internal moving parts at the proper degree of slipperiness without causing smoke or an excessive oil bill. Thermo-siphonic action is depended upon to circulate the water in the cooling system, the usual radiator and jacket reservoirs being supplemented by extra compartment in the top of the radiator, which operates to maintain the water at an even temperature at all times. The engine is sparked by a Bosch high tension magneto with fixed ignition point, there being but four high tension and two low tension wires in the entire ignition system, which, together with the elimination of the water circulating pump with its rotating shaft and pipes still further increases the simplicity of the power plant.



By the addition of the hand lever, which operates the emergency brakes, a slight rearrangement of the clutch control and gear shift mechanism has been made necessary, though it is not such as to add complication, as may be seen by the accompanying picture. The right pedal now controls only the service brake, the duties of the left pedal being restricted to the operation of the clutch, which is of the leather faced cone variety. The distinctive method of applying the clutch leather without the use of cement or rivets is retained, which feature, it is pointed out, makes it a simple matter for other than skilled hands to apply new facing in case of failure of the old through continued use. Both sets of brakes

R. C. H. TOURING CAR, EQUIPPED WITH JIFFY CURTAINS

CENTER CONTROL AND LEFT STEER



BEHIND THE R. C. H. DASH

Digitized by Google

are located on rear wheel drums and are equipped with equalizers. The change gear mechanism occupies its former place on the rear axle, the casing forming a unit with differential housing, thus stiffening the construction and reducing the liability of road strains and weaving causing the shafts to be thrown out of alignment. Three speeds forward and reverse are provided, the control being selective by means of an H quadrant.

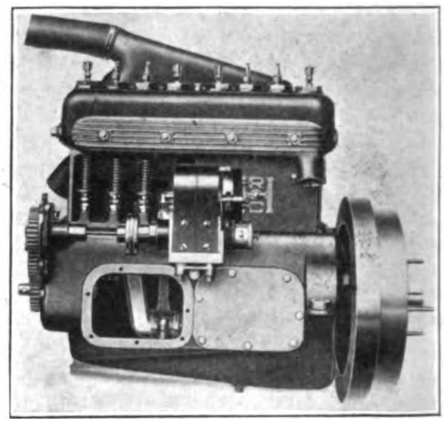
As was the case with the older models, the wheelbase of the new R. C. H. is 110 inches, the front of the car being supported on wide semi-elliptic springs and the rear of the car being carried on full elliptic members. The rear springs are "uptilted" at the front to permit the maximum degree of flexibility and compressibility and their efficient action under all road conditions is further insured by their swivel seat mountings. Tires are of the same size all around,

R. C. H. BRAKE GEAR AND SWIVELED REAR SPRINGS

32 x 3½ inches—and are of rubber tread non-skid variety. As already has been mentioned, demountable rims are regular equipment.

The British type of body, the distinguishing feature of which is its high flush sides, its "built-in" windshield and its deep skuttle dash, has been retained as a matter of course, though pains have not been spared to modify its lines wherever necessary in order to increase the comfort of passengers. The rear seat is unusually wide and measures 43½ inches, thus providing ample room for three passengers, and the front seat measures 38½ inches in width by 18 inches in depth. All bodies are finished in the exclusive R. C. H. color scheme —which is to say, the hood, fenders and running gear are black, set off by solid, dark red coloring in the body proper, and enlightened by a broad band of black around the top. Included in the electric light equipment, which takes the place of the oil and acetylene lamps and generator, are two 12-inch parabolic reflector head lamps, of the "bullet" type, two similarly shaped side lamps, a tail lamp and a 100-ampere-hour Exide storage battery.

BIGGER CADILLAC IS IN PROSPECT



Famous Car to Take Place in Powerful Class—Long Stroke Engine and New Suspension Adopted.

For the season of 1913, the line produced and marketed by the Cadillac Motor Car Co., Detroit, Mich., will be distinguished by an entirely new motor of the long-stroke type, which is very much larger than any that has borne the Cadillac nameplate in the past. The new motor will rate 50-60 horsepower, and among a number of other new features which will mark it as distinct from previous Cadillac products it will be equipped with an automatic governor, which is calculated properly to proportion the quantity of "mixture" admitted to the cylinders under normal and abnormal running conditions, thus affording the motorist automatic solution of a problem which has very often proven difficult for drivers of cars.

The newness of the power plant is carried even to the method of mounting, which is a radical departure from anything else of its kind. Though the plan hinges on the idea involved in three point support, it is said the arrangement of the supporting bearings is such as to reduce vibration and the possibility of damage through frame weaving to a greater extent than ever has been possible before. Briefly, the third point of support, which is at the front of the engine, is arranged near the top of the cylinders instead of near the crankshaft, as usually is the case.

Corresponding to the increase in the size of the motor, the car also will be more liberal in every sense of the meaning, the body being larger and more luxurious and the wheelbase being increased five inches. Electric lights will be included, as a matter of course, the Delco lighting and engine starting system in a revised and more compact form being retained. Though the list price of the car has been increased to $1,975, it is explained that by reason of the extra equipment which is added and the better all around value that is represented, the price actually is lower than last year was asked for the smaller model.

Though the Cadillac company, in common with a number of other equally well known companies, has for some time been experimenting with a six-cylinder model, attention will be confined for the present to the production of the new four-cylinder model, deliveries of which it is expected will be commenced about August 1.

R. C. H. BLOCK MOTOR

Knight Seeks to Solve Fuel Problem.

Charles Y. Knight, the inventor of the sleeve-valve motor which bears his name, is unusually fortunate in his ability to keep in the limelight and to make easy the work of his publicity bureau. According to the latter, Knight, born in America but now residing in Warwickshire, England, is making ready to undo Standard Oil and other gasolene "barons," which is to say that he has established a laboratory in his home garage in Warwickshire, and is conducting experiments with shale oil and "other indigenous fuels" in the hope of finding a commercial substitute for "petrol," the price of which abroad has soared to lofty heights, as is the case in America. According to his historian, Knight was "active in the United States against the oleomargarine combine, working in the interests of the dairymen for pure butter," and "as he couples a knowledge of mechanics with that of chemistry, the psychological time has arrived for an American to furnish the biggest sensation of the decade in motoring fuel." "Watch for Charles Y. Knight's shale oil fuel!" is the slogan which has been sounded.

Los Angeles Dealers Choose Greer Leader.

At its annual meeting, the Los Angeles Motor Car Dealers' Association elected the following officers: P. H. Greer, president; E. Roger Stearns, vice-president; Bonnie Berges, treasurer, and Earl Y. Boothe, secretary. In addition to these officers, the board of directors includes Paul A. Renton, Leon T. Shettler and Clarence Smith.

BRAKING POWER SCIENTIFICALLY CONSIDERED*

Retarding Power of Motor Car Brakes Reduced to Figures—Frictional Devices That Convert Mechanical Energy Into Heat—What Happens When the Brakes are Locked and the Wheels Slide—Relation of Motor Energy and Gear Ratios to Braking Power.

A car starts under the power of the motor; overcoming a certain resistance, it begins to move. The cause of this movement is the action of unbalanced forces; power is in excess of resistance. Meanwhile the motor is getting up to full power and speed, and the car begins to accelerate. That is to say, at each interval of time the velocity is higher in value than at the beginning of the time interval. In the early part of acceleration the force necessary to produce acceleration is equal to the product of mass and acceleration. This could be safely taken as constant up to the velocity of ten miles per hour. Reaching this velocity, the resistance will begin to increase with the intervals of velocity; that is, the resistance at the beginning of the velocity interval will be smaller than at the end of the interval. This increase in the resistance naturally requires an increase in the power output of the motor. If we investigate the power characteristic of a motor, we find that the maximum horsepower is generally reached at 1,000 feet per minute piston speed. As soon as we reach this point, the further increase of velocity is possible only if resistance decreases. Motor output = resistance; under such condition the car will travel with constant velocity. During acceleration, the car accumulates potential energy, due to its mass velocity; this is a capacity for overcoming a resistance.

If we wish to bring a moving car to rest, we have to consume this energy. A brake is an energy consumer. The most simple known way of consuming energy is by friction. In mechanics we term friction as the product of vertical pressure and friction coefficient.

In a given material the molecules are grouped together with a potential force. That is to say, each molecule will resist outside forces which tend to change its location or to separate it from the system of molecules. The contact surfaces of two materials placed together under a given pressure will deflect into each other. If we change the relative position parallel to the surfaces, certain molecules will break away and the force which retained them in the material will be set free. This force we observe as heat. The force which was necessary to move these surfaces under pressure is the friction resistance. The friction coefficient multiplied by the vertical pressure, gives the friction resistance. Consequently the friction coefficient characterizes the material in respect to its molecular structure, deflection into other materials and molecular potential energy. This friction coefficient will change if we change the temperature of the body, because thereby we disturb the molecular potential energy. Further, it will change if we introduce materials between the surfaces. This will disturb the quantity of deflection of the surfaces into each other. Wear of matter is the consequence of small particles being separated.

The physical duty of a brake is to turn superfluous energy into heat. The capacity

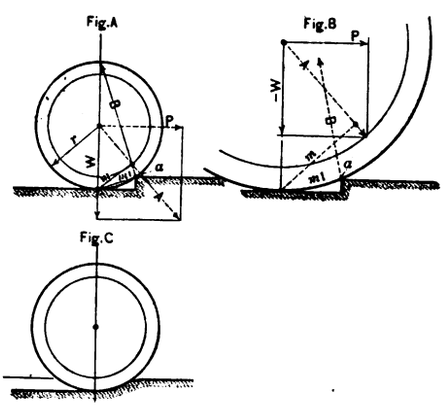

FIG. 1—HOW ROAD RESISTANCE ACTS.

of a brake to transform kinetic energy into heat units in one second is equal to the heat equivalent of the work unit, multiplied by the surface, by the friction coefficient, by the pressure on the unit surface, and by the velocity of unit distance per second.

. . .

If a wheel rim with an axle pressure could roll on a surface without any deflection, such a condition would be rolling without resistance. A wheel rim under the pressure of the axle is deflected into the ground and leaves a path. The quantity of work required to make the path of interval length in an interval of time is the measure of work consumed by resistance.

In Fig. 1 C represent the method of action of the resistance. In Fig. A if we imagine the ground resistance concentrated at the point a, then to make resistance and effort equal would require the following balance:

$B \times m_1 = A \times m$, where B = the effort of resistance; M = the lever of resistance; W = weight of car; A = the actual effort of the car, produced by the two components of P and W.

From this we see that r, radius of wheel, must be taken into consideration, because resistance is a function of the radius, of the weight, of the velocity, of the axle pressure and of two constants, one of the latter varying with the velocity. To illustrate the influence of radius shown in Fig. B, taking the same weight W and the same P,

$A \times m$ is greater than $B \times m_1$

From these many variable quantities, we can readily see that determining road resistance by any approximate formula or by any values given by tables taken from experiments made on a certain car is a very uncertain method.

During the designing of a motor car, it is very advantageous to know the accelerating condition, as giving data of the resistance variation at different speeds. Such a curve assists in fixing the gear ratio, because this is a function of both the resistance and the motor characteristic. Furthermore, it gives sufficient information as to the necessary brake capacity of the car.

The speed-time curve (Fig. 2) merely illustrates the acceleration and retardation of the car. It is not necessary for brake calculation. It is plotted so that the time integral is distance traversed. In Fig. 2 tangent O A, to the speed-time curve, is the acceleration with constant force and resistance. O B is the acceleration or speed-time curve. This is plotted so that the change of resistance with constant force in the time interval will produce a variable acceleration a. When the car reaches a velocity of ten miles per hour, we may assume that the motor will develop normal horsepower; meanwhile, the motor developing full horsepower, the car begins to accelerate. During the early part of acceleration the power is in excess of resistance. This excess unbalanced power will cause acceleration. At a certain velocity the car reaches a constant velocity. This velocity is on the line B C. While reaching this velocity, the car accumulates an energy which is capable of acting against retarding resistance before being brought to a rest. The capacity of this work equals the energy which was used to bring the car from the state of rest to this actual velocity. The value of this work is

$$M \times \frac{v^2}{2} \text{ foot-pounds}$$

At the moment when we disconnect the motor we will have a resistance which will retard at the rate C D. This being the action of the smallest resistance the travel

* Paper to be read at the annual summer meeting of the Society of Automobile Engineers, June 27-29, by S. I. Fekete, of the Hudson Motor Car Co.

Digitized by Google

will be the longest; it will take the longest time to consume the energy had when disconnecting the motor. This action of resistance we call the minimum brake effect.

The possible maximum braking effect on a car is the locked condition of the wheel. In such case resistance is equal to adhesion and the rate of retardation is shown by the curve C E in Fig. 2. The requirements of a set of brakes are those shown by a curve near the maximum brake, as indicated by line C F. Between C D E C are all the possible brakes within the limits of brake maximum and brake minimum.

The total resistance of car motion is the sum of air resistance and road resistance.

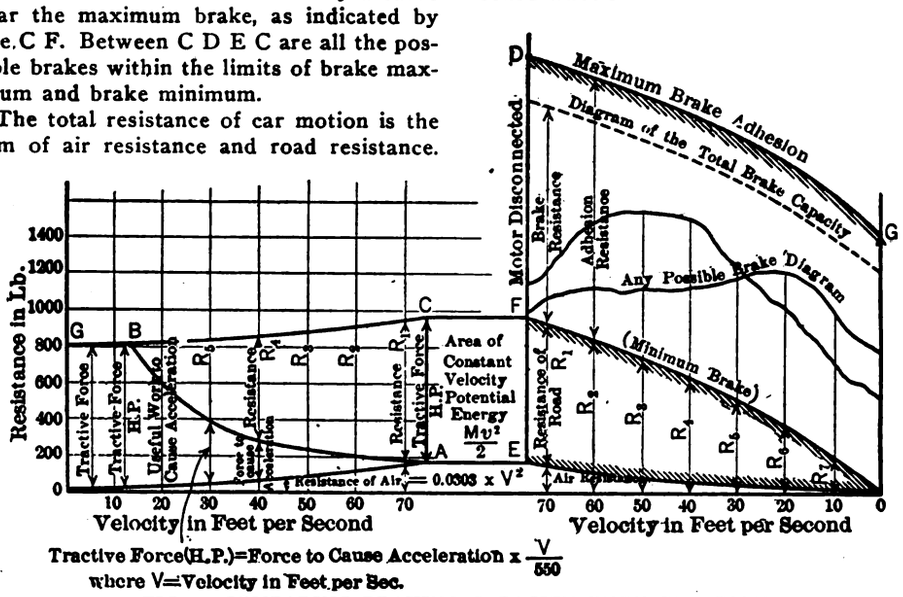

FIG. 3—COMPARING BRAKING CAPACITY WITH TRACTION

The air resistance = $0.0303 \times V^2$, where V = velocity in feet per second. These values are plotted in the curve O A (Fig. 3).

The road resistance may be determined by the acceleration. Suppose the motor develops normal horsepower and a constant tractive force; this will give a straight line G B which represents the tractive force in the diagram of 800 pounds, given by a 25-horsepower motor. Up to the velocity of 14 feet the accelerating force is constant. From point B we may assume a constant tractive force and a constant horsepower output. Therefore curve B C is parallel to the air resistance curve O A. . . .

In Fig. 3 ordinates in the area of B C A will give the resistance due to the velocity. Area C A E F represents the run with constant horsepower and constant resistance. If in D F E we disconnect the motor, we can plot the curve of the minimum brake by first tracing over the curve of air resistance; to this we give the resistance taken from the other side of the diagram (ordinates between B C A). This line represents the resistance without brake. To get the distance traversed when the car comes to rest,

$$\frac{MV^2}{2} = \text{mean resistance} \times \text{distance}$$

$$\frac{Mv^2}{2} = \text{foot-pounds energy} = N_1$$

$$\text{Distance traversed} = \frac{N_1}{\text{Mean resistance}}$$

$$\text{Mean resistance} = \frac{R_1 + R_2 + R_3 + \ldots Rn}{n}$$

The braking effort is the sum of minimum brake plus the action of brakes. The maximum brake is adhesion plus minimum brake.

First—Road resistance can be determined by the acceleration, the power output and the weight of the car.

Second—The ideal braking capacity of a car should be near to the retardation due to locked wheels.

The braking resistance given by the tangenital effort of a brake is equal to

$T \times R = Re \times R_1$, where T = tangenital effort; R = radius of brake drum;

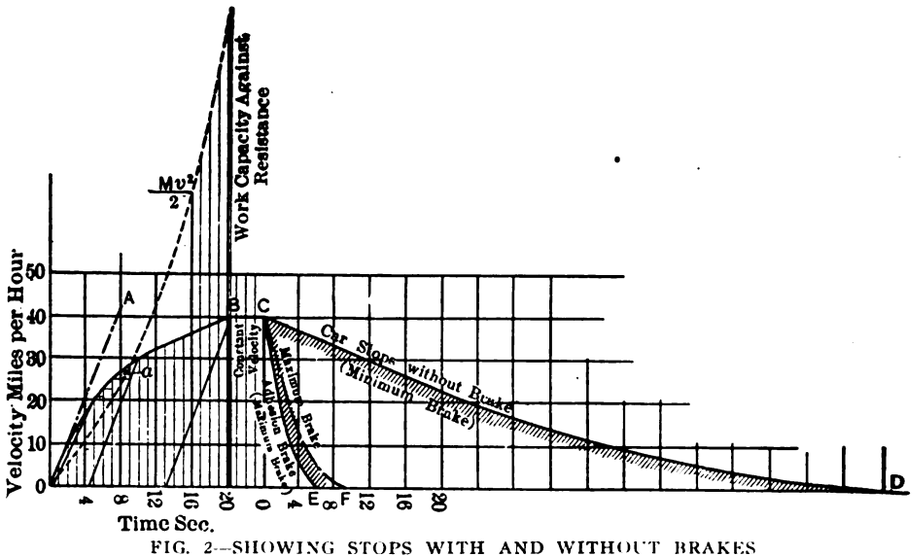

FIG. 2—SHOWING STOPS WITH AND WITHOUT BRAKES

Re = braking resistance; R_1 = radius of wheel.

Damage Claimants Gain Advantage.

While few favorable results in the main have attended the efforts to get some one finally to pay for damages sustained three years ago by William Fickert when he was struck in New York City by a taxicab owned by the Willis Cab & Auto Co., the prosecutors of the action gained an advantage this week when Judge Lehman in the Appellate Term of the Supreme Court for New York county rendered a decision favorable to the Fickert side of the argument and ordered a new trial. The case now is entitled Willis Cab & Auto Co. vs: General Accident, Fire and Life Assurance Corporation and is brought by the cab company, against which a judgment for damages was secured, to force the insurance company, which carried the cab company's accident insurance, to pay the claim. The first trial resulted in a decision against the cab company, the insurance company being awarded a counterclaim of $370 for unpaid premiums. This decision is reversed.

Uncle Sam Rules on Imported Charts.

When is a chart not a chart? was substantially the question decided last week by the Board of United States General Appraisers as the result of a protest filed by George W. Sheldon & Co. against the duty levied by the collector of the port of Chicago, whom the appraisers' board unheld. The merchandise consists of articles of paper lithographically printed, which exhibit in a pictorial manner the outline, form and mechanical features of either a locomotive or an automobile. The various parts are accurately shown by superimposed paper flaps arranged in proper order, and which are hinged so that they may be turned back to show the interior mechanism of the machine or engine. The goods were assessed with duty at 25 per cent. ad valorem under paragraph 416 as "charts" and they were claimed to be dutiable at 20 cents per pound under paragraph 412 as "articles of paper lithographically printed." While the witness for the importers described the articles as lithographic models, the board is of the opinion that these graphic reproductions are fairly within the ordinary meaning of the term "charts," as they are designed for the use of students and are in no different class than the anatomical charts which had been passed upon in a previous abstract.

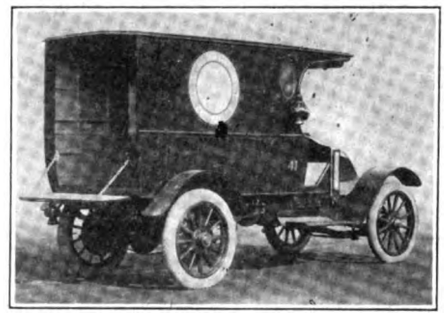
INVENTOR'S STATUS ONE OF HONOR

Benefactor Rather Than Beneficiary and Ranks With Author—Standing Recalled from High Patent Authority.

"In these days of ignorant and sarcastic criticism of the patent law of the United States, of owners of patents, and of inventors generally, it is refreshing to read the remarks of Albert H. Walker, Esq., the author of 'Walker on Patents,' the first edition of which was published in 1883," writes Milton Tibbetts of the Packard legal staff, "and whose remarks have come down through the several editions to the present day, as follows:

"'The right of property which an inventor has in his invention is excelled, in point of dignity, by no other property right whatever. It is equaled, in point of dignity, only by the rights which authors have in their copyrighted books. The inventor is not the pampered favorite or beneficiary of the government, or of the nation. The benefits which he confers are greater than those which he receives. He does not cringe at the feet of power, nor secure from authority an unbought privilege. He walks everywhere erect, and scatters abroad the knowledge which he created. He confers upon mankind a new means of lessening toil, or of increasing comfort; and what he gives cannot be destroyed by use, nor lost by misfortune. It is henceforth an indestructible heritage of posterity.



"'On the other hand, he receives from the government nothing which cost the government or the people a dollar or a sacrifice. He receives nothing but a contract, which provides that for a limited time he may exclusively enjoy his own. Compared with those who acquire property by devise or inheritance; compared with those who acquire by gift or marriage; compared with those who acquire property by profits on sales, or by interest on money; the man who acquires property in inventions, by creating things unknown before, occupies a position of superior dignity. Even the man who creates value by manual labor, though he rises in dignity above the heir, the donee, the merchant, and the money-lender, falls in dignity below the author and the inventor. The inventor of the reaper is entitled to greater honor than his father who used the grain cradle; and the inventor of the grain cradle is entitled to greater honor than his ancestors, who, for a hundred generations, had used the sickle. Side by side stand the inventor and the author. Their labor is the most dignified and the most honorable of all labor; and the resulting property is most perfectly theirs.'

Selling Drop-Hammers by Sample a Reality

Heretofore considered impossible, selling drop-hammers "by sample" has become a reality. L. M. Scofield, one of the Billings & Spencer Co.'s salesmen, is performing the apparently impossible feat. Of course, he is not carrying the 5,000 or 10,000 lb. article, but to assist his mission the famous Hartford (Conn.) manufacturers have evolved a miniature drop-hammer, which is an exact duplicate of the real thing. The miniature weighs but 16 lbs. and is of such proportions that it can be carried as readily, or even more readily, than the sample case of the average drummer.

Motor Cars That Help Ice Cream Trade.

That the speed of the motor car makes it especially satisfactory for delivering commodities of a very perishable nature is a fact that is rapidly gaining recognition. Possibly there is no commodity that is so perishable, at the time when it is most in demand, as ice-cream, and the use of motor vehicles by ice-cream manufacturers, as might be expected, is growing apace and giving rise to considerable ingenuity. Among the latest installations made for ice-cream delivery is a fleet of five cars built

by the Lippard-Stewart Motor Car Co., of Buffalo, for the Hoefler Ice Cream Co., of that city.

The cars are of the standard Lippard-Stewart capacity of 1½ tons, and are fitted with bodies designed especially for carrying the big tubs in which the sweet stuff is packed in ice. The floors are covered with a water-tight sheathing of zinc to keep the corroding brine away from the metal parts of the car, and the zinc, in turn, is protected by oak gratings, upon which the tubs rest. It is highly probable that if there was any thermal value in what is called a warm color, the ice-cream would stand a very slim chance of reaching its destination. The bodies are painted a vivid orange, with purple striping, and the Hoefler trade mark appears on the panels in purple and white.

Repairing Holes in Aluminum Castings.

A small hole in an aluminum casting, such as a gearbox or a crankcase, can be repaired by drilling out the hole to make it round, countersinking it on both sides and riveting in a bit of soft copper or brass wire of the diameter of the hole, afterward filing it off flush. This is better, when it can be done, than soldering or patching, though obviously it will not answer for holes of any considerable size.

WHY ENGINE STARTERS MAY BALK

Some of the Likely Causes of Their Occasional Failure—Magneto Cams as Possible Mischief Makers.

When a device has been designed to accomplish a certain purpose and fails of that purpose, a reason, or possibly, reasons, must underly the failure. Even though the object of the maker generally may be attained, it is only by eliminating the so-called chance failures that that degree of reliability is reached where the absolute confidence of the user is gained.

So it is with the gas type of motor starter, which, owing to its extreme simplicity and adaptability, has gained high favor. It fails occasionally, and instances are known in which the failure has been stubborn; but usually it has been traced to causes which have to do either with the production of a suitable mixture in the cylinder, or the production of a spark, but occasionally the cause has not been easily found .

When starters of gas type first were applied, the chief source of trouble was the absence of a spark when the motor stopped in any other than certain set positions, and this cause of failure was more frequently the case where, for ignition purposes, the motor was provided with a magneto having a single non-vibrating coil operating through a high tension distributer which was used for starting, than where the older type of separate coil ignition was adhered to. The fault, if the apparatus was in perfect order, lay with the circuit breaker on the magneto which was held open by the cam when the motor stopped in certain positions, and although the same trouble is met with at the present time, and especially with motors with offset crankshafts which never seem to come to rest twice in the same position, most magneto manufacturers have so altered the contour of the cam that greater leeway is afforded and the circuit breaker is closed at all times save when one of the pistons just has passed the firing point, in which position, owing to the compression, it is quite uncommon for a motor to stop. The production of a spark, however, can be made possible, no matter what the position of the crankshaft, by the simple expedient of "bridging" the circuit breaker with two wires connected to a second push button positioned on the dash. By pressing both push buttons at the same time, the spark always can be produced, regardless of the position of the circuit breaker cam. Another cause of failure due to non-vibrating coil ignition is caused by the formation of a weak spark when the button is operated slowly. To obtain the best results the button should be given several rapid pushes so that the circuit is broken quickly.

Where gasolene vapors are used as the explosive mixture, the importance of a cor-

Digitized by Google

rect mixture cannot be too well emphasized. With acetylene gas, which forms an explosive mixture when mixed with air in widely varying proportions, the importance of a correct mixture is not so great. It nevertheless is important, as is remarked by the brochure, "The Passing of The Crank," which just has been issued by the Prest-O-Light Co., which says:

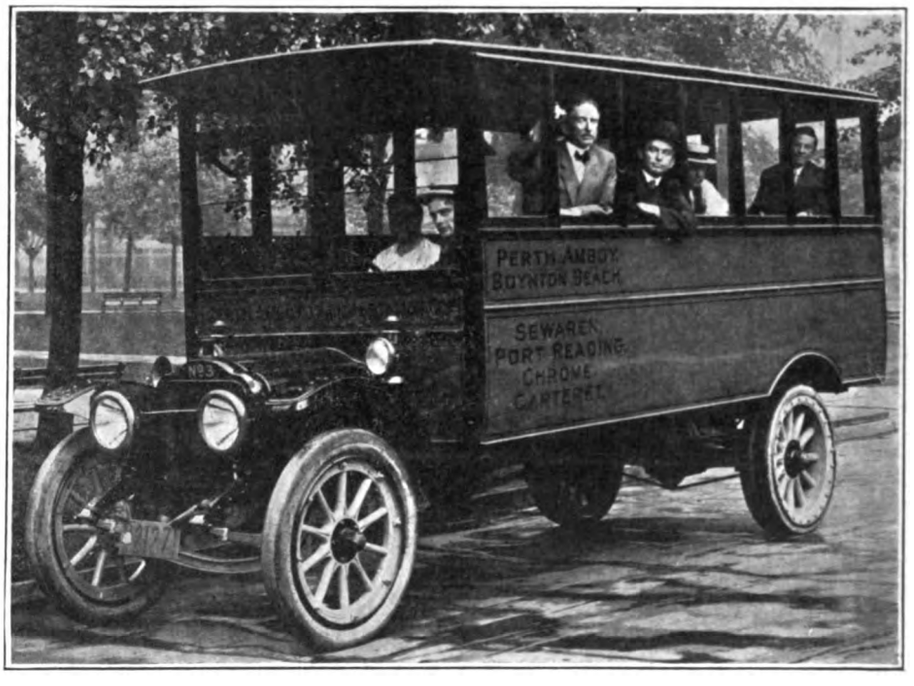
"Air is of as much importance to the successful working of the acetylene starter as is the acetylene gas, and it therefore becomes necessary that the operator provide air for starting by stopping the motor with the throttle open.

"An auxiliary air valve on the intake manifold of a motor will greatly increase the successful operation of the starter, as by its use a supply of fresh air would always be supplied by opening this valve when stopping.

"During extreme cold weather as much as three strokes of the pump is sometimes necessary, while in warm weather or when the motor is warm more than one pumpfull will only enrich the mixture to such a point that starting is difficult. Large engines require in proportion more gas than smaller ones—the proper amount for either to be determined by trial."

The use of an auxiliary air inlet positioned in the manifold cannot be too highly recommended, for although opening the throttle does allow an inrush of air, the air is tempered with a charge of gasolene vapors in correct proportion to form an explosive mixture without the addition of the acetylene. As a consequence, when the gas is forced into the cylinders, the air is over saturated with combustible gases, and a slow burning mixture which is hard to ignite is formed. If fresh air is taken in from an auxiliary air inlet, however, a more suitable mixture of air and acetylene can be produced.

With starters of the type where the gas is admitted to the manifold after the spark has been cut off and sucked into the cylinders during the dying revolutions of the motor, if the sparking arrangements are perfect and the proper quality of gas has been admitted to the cylinders, the cause of failure often can be traced to the lack of homogeneousness of the mixture, the heavier acetylene gas having settled to the lowest point in the cylinder, so that the spark wastes its energy on a mixture too lean to ignite. In this case the motor must be turned over by hand. Obviously, with starters of the pump type, the injection of another charge will remedy matters.



In starters of the pump type, where but a single pump supplies all of the cylinders, care should be exercised to keep each of the check valves which prevent the escape of the burned gas from the cylinder free from dirt and in good condition, for the slightest obstruction will cause an absence of gas in the cylinder so affected, and an abundance in the others. If the starved cylinder happens to be on the firing stroke, cranking will be necessary.

While the possibilities of a four-cylinder motor, which has been well run in so the crankshaft revolves without undue friction and which is possessed with the ordinary amount of compression, stopping on the dead center, are more remote than generally is thought, there still is that chance, and naturally an ignition starter, even though it be in perfect condition, has no effect in turning over a motor which has stopped in this position. The crank absolutely must be resorted to, and the motor given at least half a turn to bring the cylinder next in the firing order into proper position for the engine to start. Obviously if the motor is at all stiff, or if the compression is below normal, the chances of the motor stopping in a position which precludes the possibility of using the ignition starter are relatively greater.

Motor 'Buses That Do Trolley Car Work.

The absence of adequate facilities for the transportation of passengers between Perth Amboy, N. J., and neighboring towns has led to the establishment of a motor 'bus line that is carrying passengers between Perth Amboy, Boynton Beach, Sewaren, Port Reading, Chrome and Cartaret. The equipment consists of chassis of the 1½-ton commercial type, built by the White Co., of Cleveland, O., with 18-passenger bodies, fitted for use all the year round. Electric fans are used for cooling the interiors in hot weather, and for winter journeying heating systems will be employed. It goes without saying, in this age of comparative luxury in motor car building, that the new 'busses are fitted with electric lights and extremely comfortable upholstering.

Perth Amboy, which is the headquarters of the new 'bus line, is not particularly well provided with transportation, for street cars are barred from some of the streets, and there are not many lines convenient to the town. The 'bus line therefore fills a gap that was much in need of filling. It is expected that in the near future the service will be extended by the addition of more vehicles and that other towns will be included in the routes covered.

WHITE MOTOR 'BUS IN NEW JERSEY SUBURBAN SERVICE

Des Moines to Fix Taxicab Rates.

Because the taxicab chauffeurs in Des Moines, Ia., have been unrestricted in the past as to the rates they should charge and have in numerous instances ridden roughshod over protesting passengers who objected to the exorbitant flat rates asked, the City Council has under consideration a measure for the regulation of this traffic. The measure will, it is said, be passed and be put into operation before August 28, when the Iowa State Fair is held. It will require all cabs to have taximeters, and fixes rates as follows: For one or two passengers—First two-fifths mile, 60 cents; each additional one-fifth mile, 10 cents; each four minutes' wait, 10 cents. Special rates not yet decided upon will be made for four and six passenger cars. The rates on four passenger cars per hour probably will be $4.

This is 90 cents for the first mile and 50 cents a mile thereafter.

United States Tire for Electrics.

The United States Tire Co. has added to its productions a pneumatic tire especially designed for use on electric cars and guaranteed for a life of 5,000 miles. In addition to its durability, the new electric vehicle tire is built with a view to economy in current consumption, and the manufacturers claim for it an efficiency of from 20 to 25 per cent. over the gasolene car type of pneumatic tire in this respect.

THEORY AND PRACTICE IN SPRING DESIGNING*

Importance of Experimental Work in Evolving Luxurious Motor Car Suspension—Spring Steels Considered; Vanadium Alloys Favored Because of Freedom from Effects of Fatigue—Constructional Details and Tests That Bring to Light Hidden Defects.

The design of a spring intended for motor car use presents many difficulties not found in one designed for horse-drawn vehicles or railroad service. The horse-drawn vehicle is built for the same roadbed as the motor vehicle, but speed is not a factor of its design, and although the railroad car is designed for speed, it makes it on a smooth, comparatively unresisting surface.

The ideal automobile spring must fulfill three important conditions: first, it must have sufficient resistance and elasticity to support its maximum load without its shape being permanently altered; second, it must be stiff enough to take care of its heaviest work and at the same time be not too unyielding to slight unequalities of the road; and third, it must decrease the resistance of rolling.

The first consideration in spring design is the steel composition. The ordinary spring steel lacks strength and elasticity and has not the resistance-to-fatigue characteristic of some of the comparatively recent alloy steels. Manganese, nickel, silicon, chromium, vanadium and high carbon steels are used to a greater or less extent, but the best results seem to be given by springs made of alloy steel composition, such as chromium-vanadium, nickel-chromium and silico-manganese. Of these the vanadium alloys are to be preferred. But no matter how good the steel primarily, the secret of the steel spring lies in the end in the heat treatment. A recent comparative table of the physical properties of vanadium and other crucible steels gives the following peculiar properties of vanadium steel. The different steels were oil tempered at 1,500° F. and drawn to 600° F.

	Tensile Strength. Pounds Per Sq. In.	Elastic Limit. Pounds Per Sq. In.
Carbon	126,300	101,100
Nickel Chromium	150,300	134,500
Nickel Chromium Vanadium	163,700	152,300
Chromium Vanadium	233,090	210,500

Vanadium steel is practically non-fatiguable and consequently does not become crystallized under the repeated shocks to which a spring is subject. According to one authority, Wm. E. Snow, from one of whose articles the above table was taken, a crucible carbon steel spring was broken by 125,000 alternations of the testing machine, while the chromium, vanadium steel spring withstood 5,000,000 alternations and remained unbroken.

In taking up the design of the spring as regards shape, number and thickness of leaves, etc., the use of existing formulae must be regarded as merely a basis for determining just what is required under the known fixed conditions. By experimentation alone can a spring be built most nearly approximating the ideal for its particular case. There are certain fundamental rules which must be followed in all cases, but no formulae can be depended upon to give the best results under the varying conditions of motor car use. A long spring is more limber than a short one. The narrower the spring the more limberness it has. Increase the number of leaves and the stiffness is increased. The more the angle of the spring curvature arc is decreased the stiffer the spring becomes. The spring's resistance to load also depends on the thickness of the leaves. A spring of a given thickness composed of thin plates is much more elastic than one composed of a comparatively smaller number of thick plates.

In regard to the various types of springs in vogue at the present time, the following table was made up from statistics of recent pleasure car models:

Front Springs.	
Semi-elliptic	91 per cent.
Full-elliptic	4 per cent.
Miscellaneous	5 per cent.
Rear Springs.	
Three-quarter-elliptic	58 per cent.
Semi-elliptic	19 per cent.
Full-elliptic	8 per cent.
Three-quarter-platform	10 per cent.
Miscellaneous	5 per cent.

In commercial car practice there is little uniformity, due probably to the relatively recent development of this part of the industry. Semi-elliptic and platform springs are in more general use.

In the design of spring leaves there are several important factors to be considered. Each leaf should be so tapered from the center outward that strains set up when the springs are in action may be distributed gradually. In the same manner the leaves taken collectively should have the same resulting taper, that is, the bottom or top leaf, as the case may be, should be the longer, each succeeding leaf being shorter in length, so that under the load the whole spring will approximate a true arc. In going over a rough road, springs are subjected to considerable side-sway. To take care of this it is advisable to have some means of preserving alignment. Various methods are available. Near the end of each leaf there may be cut a slot into which projects a bead from the leaf underneath; or at the same point there may be formed a rib having a longitudinal movement in the indentation formed by the making of a rib in the leaf above. These ribs and slots should be so placed that each is covered by the next leaf above, resulting in their being out of sight and free from dirt. There is little difference in the comparative value of the shape of the leaf points. The round bevel end is in most common use. Springs more than two inches wide should not have French or diamond points, as they entail unnecessary waste. In most cases the long leaf supporting the master leaf should have square points, especially with a high cambered spring, in the case of which the torsional strain on the master leaf is considerable. As a means of holding graphite or other spring leaf lubricant the leaves may be slightly concaved on both the top and bottom, and the space between filled with the lubricant to prevent rusting of the parts and to add to the wearing quality of the spring by decreasing friction.

The best results of spring suspension can be determined by experimentation only. The front end of the front spring must be anchored securely to the frame, as it takes the forward thrust load. The rear end may be allowed more or less play by means of a suitably designed shackle. The spring may lie in a horizontal plane or be somewhat inclined. In some cases raising the spring slightly at the forward end adds considerably to the riding qualities. The front end eye-bolt must be of such strength as to take care of the bearing load as well as the forward thrust load. It is imperative that this bolt be made of a steel of good anti-fatigue qualities. The front left-hand spring should be so designed in respect to strength that it will properly take care of the downward thrust induced by the torque developed in the motor, which revolves in a clock-wise direction according to the general practice. This torque rarely exceeds 150 pounds, but it is necessary to make trial for accuracy. The suspension of the rear spring depends to a great extent on the design of the chassis distribution of load, etc. If the spring takes the driving effort, the front eye-bolt must be designed to this end. At the present time about 50 per cent. of the American cars are driven in this manner.

In connection with both the front and rear springs it is advisable to so design the spring that the shackle, when the spring is

* Paper to be read at the annual summer meeting of the Society of Automobile Engineers, June 27-29, by Leavitt J. Lane, of the Pope Mfg. Co., of Hartford, Conn.

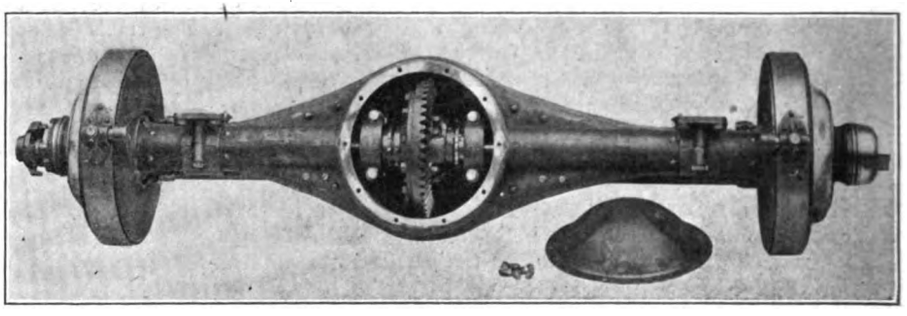
Digitized by Google

under full load, will stand in a vertical position. This is necessary for the reason that under the conditions induced by a light load the spring may rebound and cause the shackle to reverse its position, if the shackle is not kept well up to the vertical plane. It is imperative, however, that under no condition of spring action the master leaf undergo a compound strain.

Two methods may be used to hold the spring leaves in their relative longitudinal position: a bolt through the center of the spring or a band of suitable material shrunk on the center of the spring by hydraulic pressure after it is assembled. As a further means of restraining the spring leaves, the center of each leaf may be slightly indented transversely; the raised portion of each leaf made by indenting the opposite side fitting into the indentation of the leaf below. To take care of the lower leaf the band itself is indented correspondingly. The band should be as hsort as possible and still have sufficient strength, as any increase in length decreases the effective play of the spring. A dead-soft iron is recommended for these bands. When center bolts are used they must be as small in diameter as consistent so as to not weaken the spring too much by drilling through its center. The head of the screw should be of sufficient diameter to afford a good holding surface on the top of the spring.

The spring clips holding the spring to the axle should be of the best alloy steel and be placed as closely to the axle as possible so as not to interfere with the resiliency of the spring. The calculation of the size of the spring clip shank is a rather difficult matter, owing to the varying conditions for which they must be designed. . . . A prominent spring maker recommends the following sizes of shanks for the clip:

Spring widths 2 inches and under.. ½ inch
Spring widths 2 to 2½ inches..... ⅝ inch
Spring widths 2½ to 3½ inches.... ¾ inch



As the most common cause of spring breakage is the failure of the clip or the loosening of the nut or nuts, care must be taken to have some good means of keeping the nuts from working loose. Either two hexagon or square nuts, one single nut and cotter pin, or a castle nut may be used, with a fine thread, preferably the S. A. E. As a further means of retaining the spring leaves in close proximity to each other and in the form of a true arc, the ends of the spring should be provided with one or more rebound clips, clinched around the leaves or clamped by a bolt.

The spring seat between the spring and the axle should conform to both the axle and the spring. A steel casting or forging is suitable, but its length should be the least possible for the same reason as given in the case of spring bands. A formula which gives the length of spring seat as equal to 2½ times the width of the spring has been used, but it can hardly be standardized. Some authorities recommend the placing of a soft metal, canvas or leather pad between the spring and seat to decrease the liability of crystallization. If leather is used it should not be over ⅛ inch thick, so that it will not give trouble when affected by weather conditions. The spring clip plates between the slip and the top of the spring should fit the spring well and not be any larger than necessary to afford a good bearing for the spring clip. A steel forging or a malleable or steel casting may be used.

After a spring is made it should undergo some suitable test before shipment. One manufacturer so designs springs that when completed the arc of curvature is slightly less than required. Then in the final test each spring is compressed until its elastic limit is exceeded and the resulting final set of the spring approximates the arc desired. After such a test a defective spring rarely gets by. Full-elliptic springs should be compressed until they come together. Aside from the final test of the spring, the steel should, of course, undergo the usual tensile strength, elastic limit and elongation tests before being used in manufacture.

Live Axle Built on Girder Principle.

While pressed steel enters into the construction of many parts of the motor car, there is no part that more severely tries out the quality of material and the form of construction than the "live" type of axle, the housing of which frequently is of pressed steel. A particularly striking example of pressed steel rear axle housing work is shown in the accompanying illustration of one of the several designs manufactured by the Metal Products Co., of Detroit. One of the chief advantages of this design is the manner in which the metal is formed into a vertical web, tapering from the enlarged central part of the housing, which encloses the bevel gears, to the spring perches. This form, which is akin to the girder principle, gives enormous strength, particularly for resisting vertical stresses, which are the chief stresses to be borne.

METAL PRODUCTS CO.'S GIRDER TYPE LIVE AXLE

An important feature is the very large opening in the rear side of the housing for the purpose of giving access to the gears and shaft bearings. A close-fitting pressed steel cover, easily removed and replaced, excludes dirt and retains lubricating oil. There is a similar opening on the forward side of the housing, but over this is bolted the extension housing that carries the bearings for the rear end of the propeller shaft and encloses the bevel driving pinion. The Metal Products Company makes other styles of axles, as well as drop-forged front axles of the standard I-beam section. All the rear axles are full floating type and are so designed that either annular ball bearings or Bower roller bearings can be fitted at the option of the user; Bower roller bearings have been adopted as standard equipment, however, by the manufacturers.

While the axle shown is made with a pair each of internal and external brakes, other types are built in which both pairs of brakes are of the external contracting variety, working side by side on a double width brake drum.

About Extension Handles for Wrenches.

A piece of pipe used as an extension handle on a wrench is a good thing, in a way, in that it makes it possible to apply a great deal of power to the work in hand. It is dangerous, however, in many cases, not only because there is a possibility of stripping the threads of the nut or bolt to which the wrench applied, but because there is considerable risk of springing or even breaking the wrench itself. Like many other things, extension handles should be looked upon with a little suspicion and used in moderation and with caution.

To Keep the Hammer Head Secure.

A hammer that is continually flying "off the handle"—literally—is dangerous as well as a nuisance; it may injure someone, probably other than the user, and it may also damage parts of the machine. The proper may to secure a hammer head is to make a saw split in the handle and drive in a wedge of soft wood. A well wedged hammer will stay wedged about as long as the hammer lasts.

How Acetylene Burners May Be Clogged.

Acetylene gas burners will become choked with carbon if the flame is allowed to die low and go out of its own accord after the generator has been turned off. The flame should be blown out.

Rosin a Help in Pouring Babbit.

If a small piece of rosin is allowed to melt in a pot of babbit before the latter is poured into the bearing, a cleaner cast will be the result.

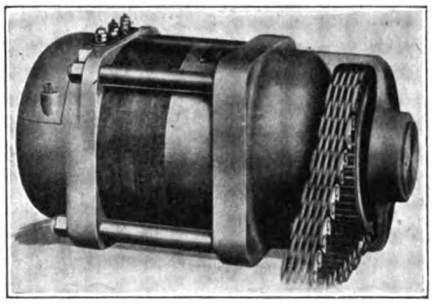
MARMON FINALLY LAUNCHES "SIX"

After Two Years of Experimentation, Indianapolis Builders Follow Popular Trend —Originalities They Disclose.

Supplementing earlier meagre details of the Marmon "six," which after two years of continued tests in which no small part of its stamina was revealed in the racing exploits of its manufacturers, Nordyke & Marmon Co., Indianapolis, Ind., the car itself formally has been placed on the market; in its lines and construction it reflects many of the individualities and charteristics that have been familiarized by the older four-cylinder "32."

Quite naturally the car is big and roomy and luxurious, as becomes the exemplification of the manufacturer's varied experience, much of which it is given out is the direct result of Ray Harroun's last year's victory in the 500-mile Sweepstakes race on the Indianapolis Speedway. The motor dimensions are 4½ inches bore and 6 inches stroke, and though the rating is but a nominal 48 horsepower, tests have demonstrated that the actual power output exceeds the indicated horsepower by upward of 60 per cent. Though the car follows quite closely the construction of its prototypes of the four-cylinder variety, it differs in one material respect, viz., it is of the left hand steer center control type.

Another of the noteworthy differences is that a new type of steering knuckle of exclusive design has been adopted. The vertical steering spindles are placed directly in the center lines of the front wheels, which construction, it is pointed out, insures easy steering, positive straight tracking and a short turning radius. The method of brake adjustment also has been slightly revised by way of permitting greater accessibility, though otherwise there are few differences from the older cars. The selective change gear mechanism remains unchanged and as heretofore is combined in a unit with the distinctive Marmon rear axle. The types of the Marmon "six" include two-, four-, five- and seven-passenger open bodies and limousine and landaulet. The bodies are mainly of cast aluminum in standard blue-black finish, and the equipment includes a complete dynamo electric lighting system, engine starter, a new type of windshield and top, and the usual complement of tools, spare parts, etc.



Motor Truck Club Plans for Growth.

Encouraged by the success attendant upon its growth and progress, the Motor Truck Club, of New York City, now proposes to enlarge the scope of its work and influence by throwing open its doors to owners as well as to makers and sellers of trucks. The by-laws are to be altered and the membership is to be enlarged so it will include three class: Active—those engaged in the industry; associate—owners, operators, garagemen, etc; and honorary—consisting of newspaper men and others interested in but not directly connected with the work. The privilege of the floor will be extended to all classes, but the power of voting will be restricted to the active class.

Aplco Develops Original System.

Applicability to a car of any make or model is a feature that in an electric car-lighting and engine-starting system has very obvious advantages. In view of the variations in chassis design, however, no little ingenious planning is required to work out arrangements that will take into account the many peculiarities of car design that must be reckoned with, and for this reason the most recent development of the driving system of the Aplco system, the product of the Apple Electric Co., of Dayton, O., is particularly interesting.

The Aplco system is of that class in which

APLCO DYNAMO-MOTOR

a small electric motor-dynamo is driven by the engine when running and charges a storage battery; the battery furnishes current for the lamps when the engine is idle and also the current which energizes the motor for starting the engine. The motor-dynamo is arranged to be connected with the crankshaft of the engine by a chain drive, or else by flexible connections when the silent chain is impracticable.

To permit this arrangement the clutches that automatically operate to throw the motor into engagement for starting or for operation as a dynamo are enclosed in a casing which forms, so far as outward appearance is concerned, a continuation of the body of the machine. This casing also contains the reducing gears. At its outer end it carries an outboard bearing for the shaft, so that the driving strains are divided between two bearings at one end. The accompanying illustration gives an excellent idea of the neatness and compactness of the design.

It has been found that in very many cars the dynamo-motor can very conveniently be carried on a bracket attached to the frame of the car opposite the point where power is taken from or applied to the engine shaft; a special bracket has been designed for the purpose. These improvements in the Aplco system affect only the method of application to cars; other details remain unchanged.

ANENT THE "OUNCE OF PREVENTION"

Factory Safeguards Recommended by Manufacturer—Most of Them Simple, Inexpensive and Readily Applied.

While the average accident in a factory or shop is probably of small consequence and not sufficient to cause any great loss of time or efficiency on the part of the workman, the compiled loss through a long train of minor mishaps probably would prove appalling if viewed only from the standpoint of a dollars and cents loss to the employer; all of which goes to indicate that precaution and prevention are, as is becoming generally conceded, profitable investments and are being widely applied.

Having this in mind and to spread the good work, the Jay A. Fay & Egan Co., of Cincinnati, O., the big machinery producers, have compiled a set of suggestions which are applicable almost generally and fit the repair shop as well as the factory. They are:

No intoxicated person should be allowed in a plant.

When men are first put to work on dangerous machines, they should be fully instructed how to operate them safely and warned from time to time to follow these instructions. Specially dangerous machines should be operated only by experienced operators, never by boys.

Slow-thinking, heavy men should not be assigned to work requiring quick thought and bodily agility.

Each workman should be made to feel that he is a safety inspector, and that suggestions from him will be welcomed.

Have plenty of room around all machines. Rail off passage-ways close to a machine.

Isolate specially dangerous machines to prevent operators' attention being diverted.

Provide plenty of light. Good illumination means efficiency, economy and profit as well as safety. Whitewash, paint, clean windows and clean lamps help greatly.

Provide good ventilation, as foul air causes loss of both mental and physical alertness.

Keep a plant well cleaned. Avoid accumulations of odd pieces and excess stock on table of machine or on the floor about it. Don't pile up work on the table of a machine.

Safety devices should be installed wherever possible. They will prevent many serious accidents, and often greatly lessen an injury which they cannot prevent entirely. Their use should be insisted upon wherever practicable. A good idea is to paint them red, to help foreman detect their non-use.

Provide all machines with means for quickly disengaging the power and the floor about them with slats, mats, grating, rosin or other efficient means to insure a secure footing.

Digitized by Google

Warning signs judiciously used will tend to prevent many accidents.

Employes should stop a machine before leaving it. Oiling or cleaning should not be done while the machine is in motion.

Workmen should be required to wear tight-fitting clothing, preferably with sleeves cut off at elbows. Rolling up sleeves, use of gloves and dressing or undressing near a moving a machine should be avoided.

Trucks should not be overloaded or material piled so that it will topple over.

Keep bandage materials within easy access of all departments, and do not allow an injured employe to continue at work unless his wound has been properly cleaned, dressed and protected.

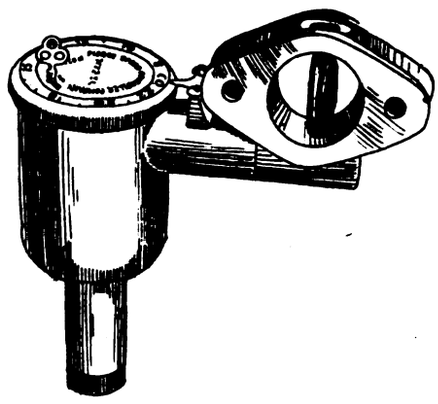
Provide the best tools and make systematic inspections of all equipment and structures.

Removing Sulphation from Battery Plates.

When storage batteries have been left standing for any length of time in a discharged state, the plates become "sulphated" or covered with a deposit of lead sulphate, which so increases the internal resistance of the battery that the output falls considerably below normal. The treatment where the sulphation is not heavy is simple, merely requiring constant charging and discharging at a slow rate. Other means for the removal of the deposit have to be resorted to, however, in cases where the deposit is heavy and hard. About the best treatment is to remove the plates from the electrolyte and wash thoroughly. Place them in a bath consisting of three parts of water, one part of ammonium hydroxide and one part of ammonium acetate, by weight. After the sulphate has entirely disappeared, wash thoroughly with water and place the plates for one hour in a bath of sulphuric acid, specific gravity 1.100, after which they are again in fit condition for reforming in the customary manner.

Hardening Parts with Heated Lead.

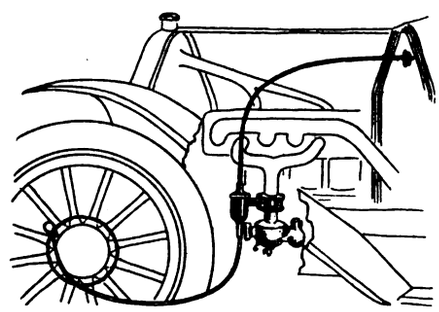
In order to ensure proper hardening of small tools and parts, they should be very carefully and evenly heated, a favorite method among quantity manufacturers being to immerse them in heated lead. When this method is used, however, the parts first should be preheated to approximately 800 degrees Fahr. and should not be permitted to remain in the lead longer than is necessary to heat them through, when they should be removed and immediately quenched in oil, water or brine, according to their substance and the use to which they are to be put.



Restoration of Burnt Tool Steel.

To restore burnt tool steel, heat the piece to a red heat, then sprinkle over it a mixture of eight parts of red chromate of potassium, three parts of saltpetre, one-fourth part of aloes, one-fourth part of gum arabic and one-fourth part of rosin. Machine tools treated this way will stand up as well as before they were burned.

GOVERNOR THAT REALLY GOVERNS



Novel Device Regulates Car Speed Instead of Motor Revolutions—Closes Throttle if Car Exceeds Set Rate.

Automatic governors designed to control the speed of motor cars are by no means uncommon, and the advantage of holding down a car, especially a commercial vehicle, to a predetermined maximum speed is so apparent that many governing devices have been devised for the purpose. With the majority, however, the governor works only indirectly on the car speed by holding

PIERCE SPEED CONTROLLER

the motor down to a maximum R. P. M. rate, without specific reference to the car speed. But there now is available a novel type of speed controller, which has for its

PIERCE CONTROLLER IN PLACE

prime object the regulation of the car speed and has no effect whatever upon the motor as long as the car is running below the maximum speed for which the governor is set. Any attempt to exceed the limit results in the prompt closing of an auxiliary throttle, which slows down the motor at once. The instrument, the Pierce speed controller, is manufactured by the Pierce Speed Controller Co., of Anderson, Ind., and is applicable to either pleasure or commercial gasolene cars.

The governor proper is enclosed in a tight brass casing and is driven, through a flexible shaft, from one of the front wheels, just as a speed indicator is driven. The auxiliary throttle, which is an integral part of the device, is of the butterfly type and is mounted in a housing which is clamped between the carburetter and the intake manifold. In the pleasure car type there is a dashboard control for the regulating dial on the top of the governor, by means of which the limit can be varied at will; in the commercial car type there is no such control. In both cases the dial can be locked at any desired speed. The accompanying illustrations show the construction and the application of the controller very plainly.

When applied to a car the governor holds the machine down to the desired speed without effort on the part of the driver. In the case of a commercial vehicle, where no little damage can be done by reckless speeding, the governor throttles the motor as soon as the road speed reaches the limit, but in case of a hard pull, where it is necessary to speed up the motor in order to obtain maximum power, the governor remains idle, being unaffected by motor speed.

One Way of "Backing Out" a Broken Tap.

It is not always necessary to drill out a tap which has been broken short off in a hole. Sometimes it suffices to bind needles into the grooves in the body of the tap by means of bare copper wire, and inserting the protruding points of the needles in the corresponding grooves in the part of the tap which is broken off. If the broken piece is not wedged too tightly in the hole it can be "backed out."

Filing Operations Facilitated by Chalk.

When filing metals for a finished surface, if the surface of the file is cleaned and given a coating of chalk, it will be impossible for a small piece of metal to stick in the teeth of the file and scratch the surface. The cleaning should be repeated from time to time and plenty of the chalk used on the file if a dead smooth surface is sought.

Simple Means of Filing Thick Washers.

To file down a washer which is slightly too thick is a job which generally is considered "mean," because of the difficulty experienced in holding the work. The best method is to imbed the washer in a block of hard wood which can be held in a vise, when the file can be applied with the greatest of ease.

"Connecting Up" That Requires Care.

In connecting up a speedometer, great care should be exercised to see that the key on the end of the driving shaft of the instrument fits snugly into the keyway on the end of the flexible shaft; otherwise, steadiness and accuracy cannot be expected.

Wrapping that Preserves Oil Stones.

An oil stone is best preserved by wrapping it in a piece of cotton cloth after use. The cloth absorbs all of the lubricant and prevents the formation of "gum" on the surface, which clogs all of the finer pores of the stone.

LONG STROKE SUITABLE FOR HIGH SPEED MOTORS*

Wilkinson Combats Time-Honored Theory That Only Short-Stroke Motors Should Run Fast—Strength of Materials, Vibration and Lubrication Factors of Importance—Theory of Bore-Stroke Ratios, Relation to Rotative Speed and Practical Effects.

In the earlier days of the automobile industry the ratio of the stroke to bore of a gasolene engine was not a much argued question. Engines of equal stroke and bore were quite common, as well as engines with longer strokes; among the latter, as I remember it, the 4¼ x 5¼ inches engine was very common. Later the square motor became well-nigh universal both in this country and abroad.

It was at this time that the horsepower formula $\frac{D^2N}{2.5}$ came into general use, being adopted first by the Royal Automobile Club of Great Britain and later by the Mechanical Branch of the Association of Licensed Automobile Manufacturers. This formula was meant only as a working one relative to the almost universal practice of equal bore and stroke. As such it served its purpose well, but today is out of date because the practice has changed somewhat. Three or four years ago the so-called long-stroke motor began to come into use abroad. Its use in England was first stimulated by a four-inch race in 1908, in which the size of the engine was limited to a 4-inch bore, stroke not being limited. As the power of a motor can be increased by increasing its size in the direction of stroke as well as bore, this naturally led to the building of motors with strokes of more or less extreme length.

Another strong incentive for small-bore long-stroke engines is the English annual inland revenue tax based on horsepower by the formula $\frac{D^2N}{2.5}$. This tax is pretty high, as can be seen by the following table:

	£	s
6½ H.P.	2	2
12 H.P.	3	3
16 H.P.	4	4
33 H.P.	8	8
40 H.P.	10	10
60 H.P.	21	
Exceeding 60 H.P.	42	

Still another incentive is that the power classification for speed and hill climbing contests all favor the long-stroke motor.

In this country our speed contests are based as far as power is concerned on the volumetric displacement, a classification which I hope to show to be correct scientifically and practically. We have, then, in this country no good reason for the adoption of any stroke/bore ratio other than that which can be shown to best meet our conditions. It is manifestly improper to classify all motors of even stroke and bore as short-stroke and all others as long-stroke.

If we take as the limits the ratios 1 and 2 and divide these into three classes we will have:

Short stroke..... 1. to 1.33 ratio
Medium stroke ..... 1.33 to 1.66 ratio
Long stroke ..... 1.66 to 2 ratio

This would be a reasonable classification for the sake of definition. Most American motors are in the first or short-stroke class.

Theory teaches us that rotative and piston speeds are limited ultimately by the strength of materials. Practice has taught us that with our present knowledge they are limited by other conditions also, such as lubrication, piston cooling and valve cooling; and that these limits are well within those set by the strength of materials. To illustrate this point, select a 4-inch bore x 5-inch stroke engine and take the explosion pressure at 325 pounds. The total pressure on the piston connecting rod and bearings will then be 4,082 pounds. It is a fair assumption that the connecting rod must necessarily be strong enough to withstand this load. Now to find the revolutions such that the inertia of the piston equals 4,082 pounds we resort to the formula

$$F = .00017\ W\ N^2\ S$$

where F = Stress set up by piston
W = Weight of piston = 3 pounds
N = R.P.M.

$$S = \text{Stroke in feet} = \frac{5}{12}$$

Reducing we have

$$N = 4500 \text{ R.P.M.}$$

I think that no one will contend that 4,500 R. P. M. would be a practical rotative speed for a 4 x 5 inch engine.

Practice again has shown that for uses in automobiles considerations of noise, vibration and life of motor have limited our maximum rotative speeds still further, to a figure considerably under that reached successfully by engines of various strokes and bores in many racing cars.

In this country to-day the practical maximum number of revolutions varies perhaps from about 1,600 to 2,000, according to the size of engine. For commercial car uses the tendency in maximum R. P. M. seems to be still more conservative.

Before studying the question in preparation for this paper it had always been the belief of the writer that the long-stroke motor could not properly be run at as high a rotative speed as the short-stroke motor. This, I think, has been the general opinion and was the view of the horsepower formula committee mentioned later. However, I have not been able to find any scientific or practical reasons supporting this view, and will attempt to explain later the reasons which seem conclusive to me why long-stroke motors may be run as fast rotatively as short-stroke motors of equal displacement.

As relating to this question, I show some of the curves and tables of the horsepower formula committee representing the Institution of Automobile Engineers, the Royal Automobile Club and the Society of Motor Manufacturers and Traders. This was a very formidable committee, but their conclusions have been very severely criticised in many quarters. They made tests of 144 engines, 101 of which tests contain all the data required for comparing the effect of stroke/bore ratio on piston speed for values of R from 1 to 1.61.

Change of Piston Speed with Variation of Stroke/Bore Ratio R = S/D Highest Recorded B.HP..

Number of Tests.	Stroke/Bore Ratio.	Piston Speed at Max. B.H.P.
15	1.00 to 1.08	1303 ft. per min.
30	1.10 to 1.20	1240 ft. per min.
24	1.21 to 1.30	1385 ft. per min.
25	1.33 to 1.44	1414 ft. per min.
7	1.50 to 1.61	1597 ft. per min.
101 engine tests		

The report of this committee, including the detail of the data and results of each engine test, is on file in the office of this society and is doubtless familiar to most of those present. I have space here for only a few of the curves from which the committee made their deductions.

The formula deduced by the committee is

$$\text{Piston speed } \sigma = 600\ (r + 1)$$

Such widely varying results do not seem to me to be an accurate basis of arriving at the proper comparative piston speeds of engines. No attempt was made to show that the conclusion is scientifically or reasonably correct. This is like trying to prove a scientific fact by popular vote. There must be some accurate way of making a proper comparison of piston speeds inasmuch as there are no unknown elements to be considered.

In order to discuss more clearly this and other questions pertaining to the paper, let us compare two engines of equal displace-

* Paper to be read at the annual summer meeting of the Society of Automobile Engineers, June 27-29, by John Wilkinson, of the H. H. Franklin Manufacturing Co.

Digitized by Google

ment but of varying stroke/bore ratios. I have selected a

4 ½″ × 4 ½″ stroke/bore ratio (1)
and 3.57″ × 7.14″ stroke/bore ratio (2)

Let us assume an equal rotary speed for both, and compare them as to vibration, noise, power, life, control, weight, cost and cooling. The engines, having the same displacement, are of practically the same weight. The crankshafts, bearings, etc., can undoubtedly be made of correct size and strength; therefore, unless we find a wide divergence in the forces set up by inertia of the moving parts,, we will not find a strong reason why one engine can be run faster rotatively than the other.

Vibration in a four-cylinder engine is caused by varying torque noticeable almost entirely at low speeds, lack of running balance of rotating parts, the effects of which increase rapidly with the speed and which are on the average a very noticeable form of vibration, the unbalanced inertia of the pistons due to angularity of the connecting rods, and other vibrations due to lack of rigidity in crankshaft, etc.

The vibration due to angularity of the connecting rods is the only one having a special relation to piston speed, and in high class engines is the one most apparent. As it increases according to the square of the speed, it is most noticeable at high speed.

$F = .00017\ N^2WS$ — represents the force set up by inertia in each cylinder; as N is equal in both engines, the comparative vibration due to above mentioned cause will be proportional to WS or to the stroke × the weight of the piston, the piston-pin and the upper half of the connecting rod. So the engine in which WS is the smallest quantity will have the least vibration. Proper comparison of weights involves similar designs and purposes. In our practice we use pistons as follows:

4½″ = 5.00 pounds
3⅝″ = 2.625 pounds
3⅜″ = 2.375 pounds

From these figures it would evidently be fair to take a 3.54-inch piston as weighing 2.5 pounds. Theoretically pistons should weigh according to the cube of the bore and would do so if made of steel and machined inside and out. Practically, using cast iron pistons, the larger would be a little lighter than the proportional figures.

The cubes of the bore of these two engines are to each other as 48.8 to 100; the practical weights, 2.5 pounds and 5 pounds are to each other as 50 to 100. It therefore seems that 2.5 and 5 must be substantially correct proportional weights. Our 4½ x 4½ rods 9 inches long weigh on the piston pin end 1.25 pounds. A similar 3.57 x 7.14 rod 14 inches long should weigh on same end 1.5 pounds; therefore

W = 5 + 1.25 = 6.25
W′ = 2.5 + 1.5 = 4
W S = 6.25 × 4.5 = 28.12
W′ S′ = 4 × 7.14 = 28.56

These figures are so near alike that we must assume the vibration in the two motors to be practically the same and that there is no basis for the belief that a long-stroke engine is a slow-speed engine on this account.

Now is there any reason to be found why the long-stroke engine cannot be run as fast as the short-stroke? About the only other point to be considered in this connection is the friction between the piston and the cylinder. This is a function of the pressure and the stroke × the co-efficient of friction, which gives the same result in both. We have then two mechanical machines in which the inertia of the moving parts sets up strains and vibrations of the same intensity and duration and which are resisted and absorbed by structures of equal weight and strength and in which the friction caused by such movement is the same.

The question of relative proper speeds is very important in connection with a proper discussion of the question. If it were conceded that of necessity either style of engine is essentially a slow-speed engine and could not be run as fast as the other, this in itself would show immediately an advantage of the one of higher speed capabilities; it would not show in any way that the high-speed motor was not just as good at low-speed work.

If we take the ordinary view of the question that the long-stroke engine must of necessity run more slowly, then to demonstrate its superiority it must first be shown that the slower speed is more desirable and next that at equal speeds it is a better engine. Further, unless it be conceded that the long-stroke motor has equal rotative speed capacity, it follows certainly that lighter, cheaper and more powerful cars can be built with the short-stroke motor.

In regard to noise, which is to-day perhaps the most important question relating to an engine, we note that both engines have the same rotative speed and the same displacement; therefore they must have the same size and lift of valves and cams. So the only point of difference relating to noise will be the greater weight of the moving parts of the valve mechanism in the long-stroke engine, due to the greater distance from valve-seat to cam; the difference is unavoidable, though small, and might amount to 10 per cent.

The question of power speeds being shown to be equal depends on the thermal and mechanical efficiency and the thermal efficiency depends on the compression and wall surface exposed to heat of combustion.

The horsepower committee mentioned admits that its figures supply no evidence of increase of mean pressure with bore, but draws its conclusion from the fact that this is apparent on different engines of the same make and that it is a well known fact that gases in large vessels lose their heat more slowly than when in smaller ones. The first deduction is open to all kinds of criticism and is admitted by the committee itself to be inaccurate. The second deduction is entirely wrong in application because the bore is not a measure of the volume any more than the stroke. The real measure of the loss of heat is the ratio of the wall surface to the volume. The committee might reasonably have said that the greater displacement of the engine, the higher the M. E. P., compression being the same. To go as far as the committee did, the rate M. E. P. from 68½ pounds per square inch in a 2½-inch cylinder, to 99 pounds in a 5-inch, seems to be justified by neither theory nor the facts.

Further, to deduce the effects of wall surface on M. E. P. from results taken at or near maximum brake horsepower, which of necessity was at high rotative speeds, where the sizes of valves, piping and carburetters are by far the principal elements in such M. E. P., indicates a lamentable lack of perception of the problem involved.

In order to eliminate as many factors as possible and to get as nearly as possible the true capabilities of the engine, the M. E. P. was taken at 800 R. P. M., which represented in every instance practically the maximum M. E. P. at any part of the curve. At this speed the effect of valve piping and carburetter sizes is largely eliminated. Of course, the effects of time of valve setting is present in the results and very likely is mainly responsible for the variations. It will be noted, however, that the results are all within a very reasonable percentage of each other and close to what might be expected. No difference traceable to the size, stroke/bore ratio or internal surface as represented by valve-in-the-head or T-head engine can reasonably be deduced.

Two figures are given, one for the bare results, the other with the size of the engine and the style of the head. Knight engines are classed as valve in the head; T.H. = T-Head, L.H. = L-Head, V.H. = valve-in-head engine.

Size of Engine.	Style of Head.	Compression. % Clearance to Total Volume.	M.E.P.
4¾ x 5½	V.H.	17	111
4⅞ x 6	T.H.	21.2	100.5
5½ x 5½	T.H.	21.2	99.5
4¼ x 5¼	V.H.	22	90
4½ x 5	V.H.	22	90
5¾ x 5¾	T.H.	21.9	89
4¼ x 4½	V.H.	22.4	95
4 x 5 15/16		23	101
5⅜ x 6	T.H.	22.7	93
4¼ x 5	L.H.	23	93
3¾ x 3¾	V.H	23	90
4 x 5⅛	T.H.	23	89
4½ x 4½	L.H.	23.5	91
4½ x 6	T.H.	24	97
4½ x 5		24	93
4½ x 4½	T.H	26	90
5 x 5½	T.H.	26	84
4 x 4	V.H.	27	83
4¼ x 5½	L.H.	29	81.5
4½ x 5	L.H.	24	81

I quote the following from a paper by Mr. L. H. Pomeroy read before the Institution of Automobile Engineers in December last:

"The writer has had two engines under observation during the past few months which only differed in respect to their valve arrangement, one having overhead valves, the other being of the orthodox type. The compression ratios were identical and every precaution was taken to eliminate disturb-

Digitized by Google

ing factors. The M. E. P. in each case over a speed range from 600 R. P. M. to 1,000 R. P. M. was substantially the same, about 96 pounds per square inch. The influence of marked changes in valve setting was also negligible."

Let us look a little into the theory of thermodynamic efficiency and see if it will give any light. The regular losses in the engine are the mechanical friction, the heat loss to the jackets and the heat going out through the exhaust. The heat lost to the jackets depends on the difference of temperature, the time and the internal surface of the engine exposed to heat. The larger the engine the greater the volume in relation to internal surface and therefore the less the relative heat loss. Lengthening the stroke of an engine decreases the thermal loss, not because the stroke is lengthened but because the volume is increased. Any increase in the size of an engine in the direction of either stroke or bore or both will decrease the thermal loss. It therefore follows that in any given size engine the less the internal surface the higher the M. E. P.,

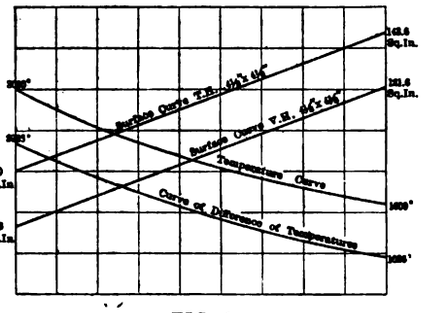

FIG. 1

but both theory and practice show this to be a very small amount. Consider the adiabatic expansion curve in two instances, one of which had no internal surface at all and the other an ordinary engine with a jacket loss of 35 per cent. and an exhaust loss of 45 per cent. The curves are shown in Fig. 2.

The difference in the mean pressure of these curves is about 15 pounds per square inch. Our practical problem then would be: If the difference between no jacket loss and the ordinary loss is 15 pounds per square inch, what is the difference in the case of two engines of a given difference in internal surface?

Our two engines, considering them as T-head with standard size valves, would have internal surface about as follows:

4½" x 4½", 80 sq. in. at beginning, 143.6 at end of stroke.
3.57" x 7.14", 71.8 sq. in. at beginning, 150.8 at end of stroke.

As the heat loss is a function of the difference of temperature and the surface, it is easy to figure that if the 3.57 x 7.14 had a jacket loss of 35 per cent., the 4½ x 4½ would have a loss of about 36 per cent. It is therefore doubtful whether there would be any difference in M. E. P.

If we had one of the engines with valves in the head, our comparison would be as follows:

4½ x 4½, 80 sq. in. at beginning, 148.6 at end of stroke.
4½ x 4½, 53 sq. in. at beginning, 121.6 at end of stroke.

Here there is a substantial difference in internal surface and we might expect a loss in one of 35 per cent. and in the other of

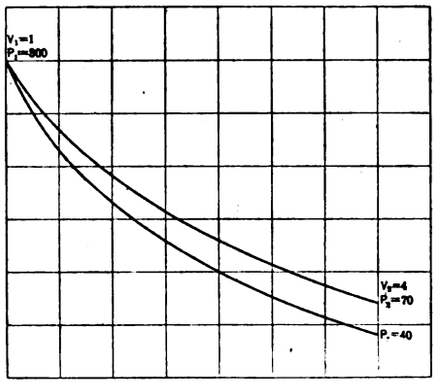

FIG. 2

50 per cent. in the jacket, which might mean 5 pounds M. E. P. difference.

I show some curves (Fig. 7) indicating the surface exposd and the difference in temperature during the stroke. The initial temperature is taken at 3,000° abs. and the terminal at 1,600° abs., and the jacket temperature at 212° and 462 or 674° abs. In the case of the T-head the engine is losing heat at the end of the stroke 66 per cent. as fast as at the beginning, and with the valve-in-the-head engine 80 per cent. as fast. Of course, actually the temperature would drop faster in the T-head motor.

This all goes to show that it takes a considerable difference of surface to make an appreciable difference in M. E. P.

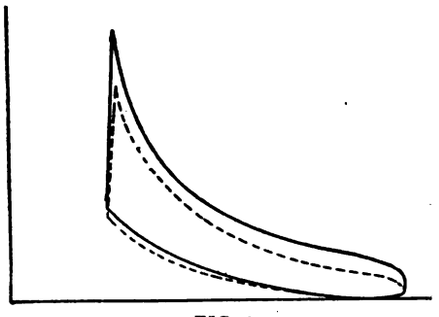

FIG. 3

Another very interesting reason why the M. E. P. does not increase with size was brought out by Mr. F. W. Lanchester, whom I quote as follows:

"There are two factors, other things being equal, that control the mean pressure—the compression ratio and the cooling loss. If we prescribe some definite limiting value to the compression ratio to be employed, then it must immediately be conceded that the larger cylinder will show a higher mean pressure, owing to its cooling losses being relatively less than those of the smaller cylinder. Thus firstly in the smaller cylinder the actual compression will be lower, owing to the greater cooling during the compression stroke, and secondly the heat losses during the combustion stroke will be greater; and so the expansion curve will fall more rapidly (Fig. 3). But as a matter of fact there is no prescribed compression value; the compression is limited by the question of pre-ignition. If an engine is given too high compression, pre-ignition will occur or short of actual pre-ignition the explosions will become of a detonating character, and the engine will be correspondingly noisy. The compression has then to be reduced. Now, the smaller the cylinder the higher the compression ratio permissible, owing to the greater cooling during the compression stroke—in fact, not only may the compression ratio be increased but the actual compression may be higher; for the temperature of the charge at any given compression is actually lower. Consequently the small engine, though sacrificing mean pressure due to its greater cooling loss, will, if properly designed, re-

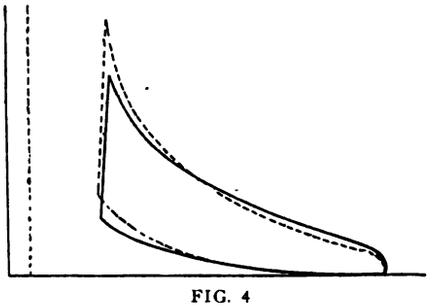

FIG. 4

ceive some compensation from the higher compression that may be employed. The comparison then becomes one as illustrated diagramatically in Fig. 4 instead of as in Fig. 3.

"It is an interesting fact that over the range of sizes commonly employed in automobile work these two influences in many cases almost exactly cancel out. Thus in the Daimler sleeve-valve engine I have found it just as easy to obtain a given mean pressure in a small cylinder (70 mm. dia.) as in a large one (124 mm. dia.). Thus to obtain (at ordinary barometric pressure) mean pressure as shown by the brake in cylinders of the diameters given, the following compression ratios were employed, the figures representing the total volume in terms of the clearance volume":

Cylinder Diameter in mm.	Ratio.
124	4.6
100	5.0
96	5.11
80	5.6
70	6.0

The maximum brake horsepower of our two engines figured from the formula of the above mentioned committee is

4 ½ x 4 ½ — 1800 R.P.M. 96 M.E.P. 55 H.P.
3.57 x 7.14 — 1534 R.P.M. 86 M.E.P. 46 H.P.

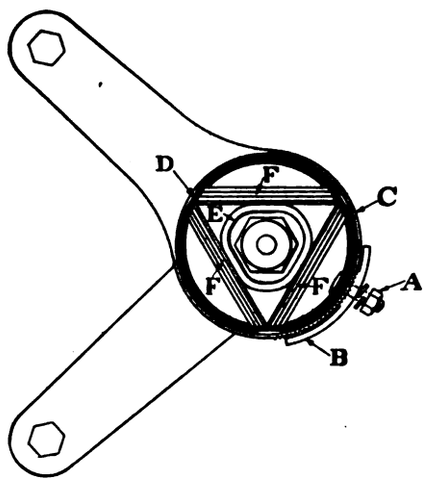
The deduction from the argument of the writer is that the variation is not worth

Digitized by Google

mentioning. It must be evident that if the figures of the committee are taken that the long-stroke engine is an inferior engine.

The mechanical friction of our two engines differs only in the friction of the wrist-pin, the crank-pin and the main journals. The piston friction being a product of the thrust, the stroke and the coefficient of friction, will be the same in the engines, as the thrust is proportional to the area of the piston and, of course, the area multiplied by the stroke is the same in both cases. Likewise the ring friction will be equal. The other frictions mentioned will be proportional to the area of the piston alone, crankshaft sizes being the same. This friction with a coefficient of .04 will be at 800 R. P. M. about 1.25 horespower for the 4½-inch engine and .75 horsepower for the 3½-inch engine, a difference of .5 horsepower.

The heat lost through the jacket is a measure of the size of radiator necessary. As to the effect of piston size on cooling, it is undoubtedly true that the larger the piston the more difficult it is to keep it cool, but the limiting feature of our present high-speed engines, with necessarily large valves, is more likely the size of the exhaust valve. It is probable that a stroke and bore ratio below 1 might soon be reached where the piston would be more difficult to cool than the exhaust valve, but we are not dealing in practice with such stroke and bore ratios. The tabulated data of American engines show the practice is to use as high compression in large engines as in small ones. So far as the writer knows there have been no experiments in regard to cooling carried on which would show us the relative effects in large and small engines. The writer has never been satisfied that if this element were taken into strict consideration, small engines would not be found superior to large ones in M. E. P. and horsepower per cubic inch of displacement.



The life of an engine is governed largely by its speed. At equal speeds there are to be noted two differences which must be considered in the design. The piston of the long-stroke engine, being shorter and yet subject to the same total friction, will necessarily wear faster. Likewise the bearings of the short-stroke engine, being subject to greater pressure at the same speed, will require more area. The friction and wear of valve mechanism cannot vary, as they should be the same in every respect.

It might be interesting to note here that any increase of weight due to increasing the life of the piston in one case might possibly be balanced by an increase in the other piston from the desire to get better cooling.

As a purely thermal question there is apparent no reason why the stroke and bore ratio cannot be carried beyond even a ratio of two. But as to mechanical design awkwardness begins to be apparent at ratios beyond 1.33; and beyond 1.5 the objections become more or less acute, running into weight and expense without any compensating features. Any extra long stroke involves too much weight in the valve mechanism and a strong temptation to too short connecting-rods to keep down the height and weight. With L-head engines a design beyond 1.33 exaggerates the valve pocket design. On the other hand, in block engines with two-bearing crankshafts long strokes shorten the distance between bearings and lessen the thrust, thus diminishing the necessary diameter of crankshafts; and in six-cylinder motors the length of motor is shortened. It might be fair in placing general limits on the stroke bore ratio to say that it is limited in one direction to 1 by the cooling limit of the piston, and in the other direction to 1.5 by the limits of mechanical adaptiveness.

Improving Shock Absorber Adjustment.

Whatever difficulties may have existed in the past with regard to the adjustment of shock absorbers, apparently they belong only to the past, so far, at least, as the Connecticut shock absorber is concerned. The latest improvement on this road-smoother, which is the product of the Connecticut Shock Absorber Co., of Meriden, Conn., is the adjusting device which is shown in the accompanying illustration.

CONNECTICUT IMPROVED ADJUSTER

To adjust the Connecticut shock absorber the car is loaded with its full complement of passengers, plus one, the adjusting nut A first having been loosened. When the passengers are all in place the nut is tightened, and the adjustment has been made. A milled segment, B, engaging with the teeth on the outside of the case C, is loosened when the adjusting nut A is turned back. This permits the ring D to turn to what is neutral position, under the existing load conditions; the cam E and the springs F are brought to the same relative position as the ring, and when the ring is locked by tightening down the adjusting nut the other parts are locked at the same time. They require no special attention, falling into place automatically when the adjusting nut is loosened.

When in neutral position the springs, pressing on the flat faces of the cam, have very little retarding effect, but upon moving either way from neutral the cam "toes" are forced against the springs with a pressure that increases with the movement away from neutral, and thus check excessive depression and rebound of the car body when obstructions are encountered.

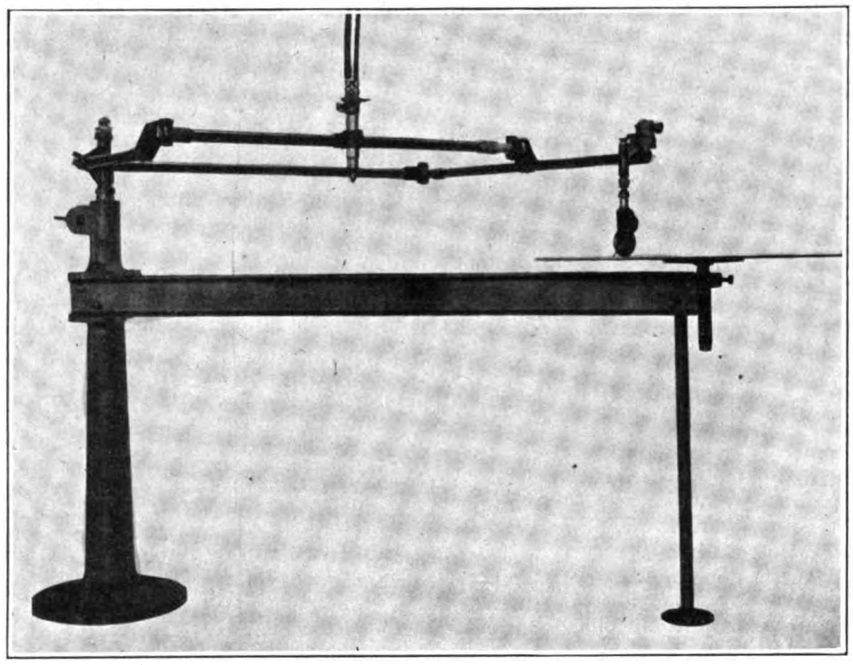
Vanadium Valuable for Varied Uses.

Where steel components of motor vehicles are subject to continual and severe vibration, to say nothing of occasional overload, it has become common practice for some time past to form these parts from vanadium steel, which, owing to its toughness and because it is not subject to "fatigue" or crystallization to the same extent as ordinary steel, has been found ideal for the purpose. That the metal really is improved by the addition of vanadium in correct proportions and that this fact is fully realized and recognized by the producers is indicated by the fact that "all vanadium steel" cars are realities, and by the general tendency on the part of an increasing number of manufacturers toward the incorporation of vanadium steel parts, even where such parts are not subject to excessive vibration and overload.

That the addition of slight amounts of vanadium to other metals which enter into the construction of the motor car and especially to the cast iron from which the cylinders, pistons, etc., generally are moulded, will open the way toward further reduction in weight and make for more durable motors, seems to be clearly indicated. Not only does the addition of vanadium to cast iron increase the strength of the product from 10 to 25 per cent., but it exercises a very strong effect on the grain of the iron, causing more even distribution of the graphite with consequent greater freedom from both hard and porous spots. Vanadium also gives an element of toughness to the cast iron which is very apparent in machining the castings. Not only does this toughness make the machining more easy and certain of success, but together with the inherent closeness of grain of vanadium cast iron makes it suitable for use in cylinder castings, piston rings, etc.

For two years back the M. Rumley Co., which makes Oil-Pull motors and farm and road tractors in its factory at La Porte, Ind., has used nothing but vanadium cast iron piston rings and is credited with asserting that no other rings can compete with the vanadium cast iron product for durability, and that no other ring will retain its elasticity under the high temperatures which are common in oil motors for so long a period as the vanadium steel ring.

Tallow that Assists Soldering of Cast Iron.



Cast iron can be soldered if the surface is first cleaned with a scratch brush, the soldering acid applied over the part to be soldered and a layer of tallow over the acid. Apply a second portion of soldering acid and solder in the ordinary manner.

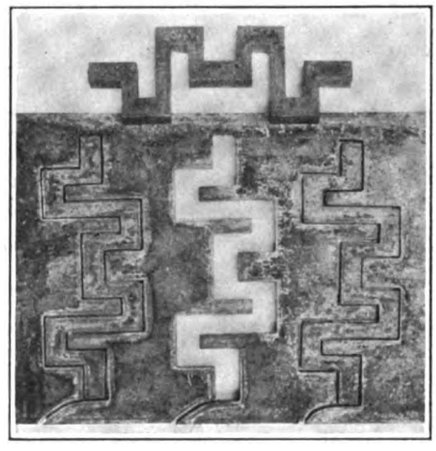
OXYACETYLENE REVIVES CUT SHAFT

Modern Apparatus Bids Fair to Popularize Once Expensive Process—Oxygraph, New Device, May Rival Drop-Forge.

To the use of special apparatus, tools and jigs, some of such simple design that they may be termed the acme of simplicity, others more intricate, but each serving to lessen the time and cost of production, can be attributed the low initial cost of the American built automobile, and each new design, or improvement of an old design, of some labor saving device which tends to increase the facility with which the completed product can be turned out, has an effect on the price of the vehicle.



OXY-ACETYLENE PANTOGRAPH FOR CUTTING METAL

Thus, in former years, when motor crankshafts were hewn from flat steel plates the operation involved the drilling of the plate several score times, and the cost was almost prohibitive. Hence the cheaper process of drop forging the crankshaft became the more general practice. With the introduction of the oxyacetylene process of cutting metals, however, the cost of producing crankshafts from flat steel slabs was greatly reduced and each improvement of the process of cutting metals by burning, or of the method of applying the process, has given rise to a display of new interest in the manufacture of crankshafts from the plate, of which the machine shown by the accompanying illustration is a direct development.

The device is made by the Davis-Bournonville Co., which has offices at 88 West street, New York City, and shops at Marion, N. J., and which for some time past has made torches and apparatus incidental to the application of the oxyacetylene process. The new device is termed an Oxygraph and has been designed with a view to facilitating the operation of plate cutting to the last degree. To this end the torch, which is of special design for use of the oxygraph, is carried on one leg of a pantograph and the movement is controlled by the operator through the intermediary of a tracer with which he follows the lines of the cut directly on the blue print and the usual complement of connecting links which go to make up the pantograph. Thus the process of laying out the work to be cut from the plate is dispensed with.

The apparatus consists of a frame supported by a pair of legs on which the work is supported directly under the nozzle of the vertical torch, a flat table on which the blue print or sketch of the work in hand is fastened, and a motor driven pantograph which carries both the tracer and the torch. The operator places the drawing on the tracer table, turns the current through the motor and follows the lines of the drawing with the tracer. The torch follows a similar path over the work, but the distances the torch travels are half those followed by the tracer.

OXYGRAPH WORK

Not only can curves be cut, but right angle corners as well. With oxygen of high quality, the kerf is very narrow and the cuts clean and sharp. The slight width of the cut can plainly be seen from the second photograph, which shows three crankshafts cut from a three-inch steel plate. It is stated that the apparatus will cut three-inch plate at the rate of six inches a minute.

How Agricultural Motors Will Be Tested.

In the Canadian agricultural motor trials, which will occur in Winnipeg, July 3d to 30th, the tests will comprise brake tests, ploughing tests, and such others as the judges may deem essential. The brake test of the machines will mean a two hours' run at their greatest load consistent with economy. Subsequently, a test will be made of the maximum horsepower the engines will develop for thirty minutes.

The ploughing test may extend over a period of five hours or longer, the depth of ploughing to be uniform, and as directed by the judges. Competitors may use any kind of plough they wish. In connection with this test the quality of the ploughing which is to be judged by prominent agriculturalists, shall have special reference to evenness of depth of furrow, uniformity of thickness of the furrow slice, straightness of furrow, finish at the ends, etc.

In respect of design and construction the points that will be considered will be the protection of the working parts from mud and dust, dustproof bearings, accessibility to all parts, such as valves, igniters, bearings, ease of manipulation, such as starting and stopping, reversing, and the general handling of the engine.

The trials constitute a feature of the Canadian National Industrial Exhibition, which is held annually in Winnipeg, and which is largely responsible for the fact that in Western Canada the use of tractors and other farm motors is more widespread than in any other part of this continent.

Antelope Finally Secures Its Inning.

Animals of practically every variety, along with numerous other creatures and things, have played somewhat similar parts but only recently has a happening in Texas squared up matters by giving the much neglected antelope a boost. Hitherto this species of four-footed beast is said to have been rather "sore" because it was overlooked, while bears, coyotes and the rest were appearing regularly in automobile news columns. George McEnitre, of Sterling City, Tex., is the man to whom the antelope is indebted. He is credited with the story of how he finds considerable sport in chasing antelopes over the prairies and catching them alive. In his Franklin car he caught the last one but a few days ago.

1,009,837. Water-Jacketed Cylinder for Internal Combustion Engines. Raymond L. Gruber, Milwaukee, Wis. Filed Feb. 9, 1911. Serial No. 607,523.

1. In an internal combustion engine, a cylinder having one longitudinal half water-jacketed, and the other longitudinal half exposed to the atmosphere and provided with atmospheric cooling surfaces.

1,009,941. Internal Combustion Engine. Walter S. Thompson, New York, N. Y. Filed May 20, 1910. Serial No. 562,415.

1. In an internal combustion engine, the combination with the compression chamber of the engine having an opening in one of its walls, of a rotary valve having a port adapted to register intermittently with said opening and to open thus communication between said opening and the interior of said chamber, and means for varying, at will simultaneously both the points of opening and closing of said communication relative to the cycle of operation within the cylinder of the engine.

1,010,031. Elastic Hub Wheel. Cesare Feroci, Rome, Italy. Filed Dec. 26, 1908. Serial No. 469,346.

1. An elastic hub wheel comprising a hub having radial chambers on its circumference, an inner rim having radial chambers on its inner circumference, spiral springs having their ends resting in the chambers in said rim and hub, and V-shaped rubber blocks located between the adjacent springs and having their ends resting in the chambers in the rim and hub.

1,010,061. Puncture Proof Tire. William W. Lower, Tyrone, Pa. Filed June 24, 1911. Serial No. 635,173.

1. The combination with a wheel felly and rim having clencher flanges, of a tire comprising a resilient casing adapted to interlock beneath said rim flanges, a circumferential series of pairs within the casing, the plates of each pair being radially disposed, cushioning means interposed between the plates of each pair, tending to maintain the casing in distended position, and means operable through the rim to cause the inner plates to spread laterally to interlock the casing with the rim flanges.

1,010,066. Carburetter. Edward C. Newcomb, North Scituate, Mass., assignor to Newcomb Carbureter Co., a Corporation of New York. Filed Oct. 15, 1910. Serial No. 587,145.

1. A carburetter comprising a member having a multiplicity of air supply ports, a valve for controlling said air ports, said parts having a relative movement, the total effective port opening produced by any such movement being substantially proportional to the movement, a member having a fuel supply port, a needle for controlling said fuel port, connections for producing a relative movement between the fuel port member and the needle proportional to the relative movement between the air port member and valve, and means for maintaining under the normal conditions of operation a substantially fixed relation between he heads acting to force the fluids through heir respective ports.

1,010,082. Steering and Controlling Mechanism for Motor Vehicles. Gustavus F. Smith, New Berlin, Ohio. Filed Mar. 13, 1911. Serial No. 614,168.

1. A steering mechanism for motor vehiclue including a rotatable hollow steering shank with a wheel thereon and having longitudinal slots in its walls, an endwise movable shank in the steering shank having a cross head with sprockets protruding through the slots, an endwise-stopped rotatable sleeve around the steering shank having an internal screw thread meshing with the sprockets, and an arm extended from the sleeve having a handle slidably fitting one side of the rim of the steering wheel.

1,010,110. Vehicle Top Bow Holder. Clarence L. Bair, San Francisco, Cal., assignor to Auto Specialties Manufacturing Company, a Corporation of California. Filed May 26, 1910. Serial No. 563,480.

1. A vehicle top bow holder comprising a stock having its upper end grooved to form side ears, an arm hinged to the lower end of said stock and formed with a series of lifts co-operating with the stock to provide separator sockets for the bows, said arm having at its upper end a shoulder adapted to abut the side ears of the stock when the arm is closed and a projection extending from said shoulder and arranged to project between said ears of the stock, a contact piece on said arm in rear of said shoulder, a locking lever having a contact lug to lock behind the contact piece of the arm, and a spring link having its ends pivotally connected to the upper portion of said arm and to said locking lever.

1,010,158. Automobile Fire Engine. Leon B. Lent, Brewster, N. Y. Filed Mar. 18, 1911. Serial No. 615,266.

1. In an automobile fire engine, the combination with a frame and supporting wheels, of a motor, a main shaft driven thereby, transmission mechanism between the shaft and wheels, and a pump directly driven by said shaft.

1,010,184. Carburetter. Carl F. Schulz, Brooklyn, N. Y. Filed Jan. 19, 1911. Serial No. 603,491.

1. A carburetter embodying a fuel inlet valve and provided with an air inlet opening and a mixture outlet opening, an air admission valve arranged to admit air from the air inlet opening into the carburetter whereby it may pass to the mixture outlet opening, said valve being movable by suction toward open position, and pressure-controlling means arranged to balance the pressure of the suction on opposite sides of said valve, at predetermined positions thereof.

1,010,185. Carburetter. Walter F. Schulz, Corona, N. Y., assignor of one-half to Carl F. Schulz, Pennington, N. J. Filed Apr. 24, 1908. Serial No. 429,052.

1. A carburetter having a mixing chamber formed with an air inlet port, a fuel inlet passage open at both ends and communicating at one end with the outer air and at its other end communicating with said mixing chamber, said air passage having imperforate walls, an inspirator located in the air passage, a suction valve controlling the admission of air through the air port, and a spindle movable with the valve and depending therefrom into the air passage, said spindle controlling the outlet from the inspirator.

1,010,230. Tire for the Wheels of Automobiles and Other Vehicles. William Butterfield. Dublin, Ireland. Filed Feb. 14, 1911. Serial No. 608,617.

In a wheel tire, the combination of resilient blocks arranged crosswise on the rim of the wheel, each block having a contracted central portion forming a bulb-shaped head and flanges, a holding block interposed between adjacent resilient blocks and resting on their flanges; the holding blocks having their outer surfaces within the normal outer surfaces of the bulb-shaped heads, and means for slidably securing the holding blocks to the wheel, substantially as described.

1,010,233. Starting Mechanism for Explosion Engines. Christian Christiansen, Kenmare, N. D. Filed Feb. 6. 1911. Serial No. 606,987.

1. In an engine starting mechanism, the combination with the engine shaft and a clutch member thereon, of a cranking shaft, a clutch member on the cranking shaft to engage the clutch member on the engine shaft, a hand wheel shaft parallel with the cranking shaft, a gear connection between the hand wheel shaft and the cranking shaft including a gear wheel slidably journaled on the cranking shaft, a clutch member carried by said gear wheel to engage the clutch member on the engine shaft, and a spring operating to normally disengage the two clutch members carried by the cranking shaft from the clutch member on the engine shaft.

1,010,234. Automobile Tire. Thomas Christopherson, East Helena, Mont. Filed Feb. 7, 1911. Serial No. 607,213.

In a wheel, a felly having upwardly and inwardly extending spaced flanges, one flange thereof being provided with an opening therein, a plurality of hollow metallic spring members mounted on said felly, said metallic spring members having their edges tapering toward the center of the wheel and normally bearing on one another for their entire length, the sides of said members being flared outwardly beyond the felly of the wheel to form a flat tread surface, and means for closing in said flange.

1,010,258. Combined Sectional Tire and Wheel Rim. Frank M. Henry, New York, N. Y. Filed Jan. 11, 1911. Serial No. 601,992.

1. A tire section combining a spherical body, a base secured to said body, and a projection formed on the opposite side of said body and having a flat surface forming a tread for the tire section.

1,010,273. Speed Changing Mechanism. Fred A. Law, Hartford, Conn., assignor, by mesne assignments, to The Columbia Motor Car Company, Hartford, Conn., a Corporation of Connecticut. Filed Feb. 5, 1902, Serial No. 92,677. Renewed July 8, 1907. Serial No. 382,721.

1. In combination in a change speed mechanism, a driving shaft, a driven shaft, mechanism for clutching said driving shaft to said driven shaft, transmitting means for imparting a plurality of different speeds from said driving shaft to said driven shaft including gears sliding upon the driven shaft, and means for shifting said gears, means whereby the speed of the driven shaft may be changed directly to any speed relative to the driving shaft without passing through intermediate speed positions.

1,010,340. Headlight for Automobiles. Lyman O. Amanson and Milton H. Ulrich, Miller, S. D. Filed Dec. 9, 1910. Serial No. 596,541.

In combination with the usual knuckle steering gear of a vehicle, of an internally screwthreaded tube having one of its ends

Digitized by Google

secured thereto, a screw-threaded rod adjustably carried in said tube and having one of its ends pivotally connected to the lower end of a tubular member, a coil spring in said member, a rod pivotally supported upon a portion of the vehicle and having its lower end slidably mounted in the tubular member to engage the coil spring therein, an internally screw-threaded tube pivotally connected to the upper end of said rod, oppositely disposed rods adapted to engage in said tube, caps secured to the ends of the oppositely disposed rods and provided with bolt openings, lamp carrying brackets secured to the vehicle and provided with lamp supporting arms, said arms being pivotally connected to said caps so that when the direction of the wheels of the vehicle is changed the lamps will be partially rotated.

1,010,412. Speed-Limit-Signaling Apparatus. Fabius M. Butler, David City, Neb. Filed Jan. 21, 1910. Serial No. 539,227.

1. In an apparatus of the class described, a speedometer, a series of electric contacts carried by the speedometer in the path of the movable member thereof, another series of contacts individually coupled to the contacts of the speedometer, an electric circuit including an alarm and connected on one side to the movable member of the speedometer adapted to engage the contacts thereon, means for connecting the other side of the electric circuit to any one of the second named series of contacts, a visual index, and connections between the latter and the means for connecting the electric circuit to any one of the second named series of contacts for rendering portions of the last named index member visible in accordance with the predetermined speed limit.

1,010,484. Wheel. Roman von Fabrice, Brooklyn, N. Y. Filed Dec. 23, 1909. Serial No. 534,654.

1. In a device of the class described, a driving gear provided with a hub to receive

the hub of the wheel and a plurality of hook shaped spoke engaging members to engage the spokes of the wheel.

1,010,539. Wheel Tire. Frank Vitali, Healdsburg, Cal. Filed Mar. 6, 1911. Serial No. 612,611.

A wheel tire comprising an annular base formed with a circumferential series of radial sockets, a plurality of separate cushion segments formed each with a transverse tongue and lateral shoulders, the tongues fitting in the sockets, means engaging with the shoulders for holding the segments in position, and an outer tube surrounding and held distended at all points by said segments.

1,010,560. Tire Device. Dorah W. Wilt, University Place, Neb. Filed June 7, 1911. Serial No. 631,827.

The combination with a wheel-mounted vehicle having a seat including a back, the back including a movable section which may be tilted forwardly, of a plate spaced from the back, a lid hinged to the movable portion of the back and co-operating with the plate, and upholstering for the seat, the upholstering being carried rearwardly across the lid.

1,010,566. Internal Combustion Engine. Arthur Alltree, Manchester, England. Filed Jan. 19, 1910. Serial No. 538,885.

1. In an internal combustion engine, a stationary working cylinder, having inlet and exhaust ports, a pair of segmental or half-cylindrical slide valves having ports and disposed around said cylinder; and means for operating the said segmental slide valves to bring their ports respectively into register with the inlet and exhaust ports of the working cylinder on both the up-stroke and down-stroke of the valves.

1,010,583. Gas Engine. Ray Carmichael and William Schaibley, Indianapolis, Ind. Filed Aug. 18, 1910. Serial No. 577,768.

1. An internal combustion engine including a fan-shaped explosion chamber, a rock shaft mounted in connection therewith, a piston extending radially from the rock shaft in said chamber with its outer surfaces in engagement with the walls of said chamber, means for causing explosions in said chamber, and means extending through said rock shaft and piston for supplying lubrication to the engaging surfaces of said piston and the walls of the explosion chamber.

1,010,682. Clutch. Frank Palmiter, South Bend, Ind., assignor to Indiana Anchor Fence Co., South Bend, Ind., a Corporation of Indiana. Filed Feb. 8, 1911. Serial No. 607,259.

1. In a clutch, the combination with a driving and a driven member, of a thrust member, wedge members having a sliding interlocking connection with said thrust member for positively shifting the latter in either direction, and means for actuating the wedges.

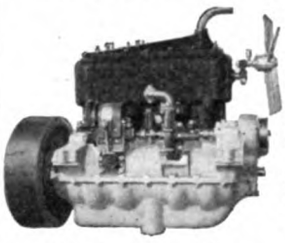
1,010,688. Spring-Wheel. John C. Rinehart, Washington, D. C., assignor to The Rinehart Resilient Wheel Company, Incorporated, Alexandria, Va. Filed Oct. 15, 1910. Serial No. 587,141.

1. A spring wheel comprising a hub, a sleeve frictionally but slidably engaged over said hub, a rim, and resilient spokes secured to said rim and sleeve, each of said spokes having a central bowed portion lying in a plane at right-angles to the plane of the wheel; in combination with means to limit the revolution of said sleeve on said hub.

1,010,714. Carburetter. George J. Zisch, Newark, N. J., assignor to Thaddeus B. Eiker, Asbury Park, N. J. Filed May 12, 1910, Serial No. 560,810. Renewed Mar. 29, 1911. Serial No. 617,720.

1. A carburetter comprising a casing, a mixing-chamber therein for the air and gasolene or the like, a valve controlling the passage of air and gas through said chamber, a rotary gasolene discharge pipe in said chamber, valve-mechanism for admitting a variable supply of gasolene to said pipe, and means for effecting the co-operative action of said valve, discharge pipe and valve mechanism; substantially as set forth.

1,010,715. Windshield. Edward L. Ackerman, Detroit, Mich., assignor of one-half to Charles E. Chamberlin, Detroit, Mich. Filed May 1, 1909. Serial No. 493,380.



In a windshield, the combination with a lower section mounted for outward rocking movement and an upper section hinged to the lower section for inward folding movement, of a double crank arm extending forwardly from the upper section, a spring connected at one end to the lower section, and a brace connected at one end to the other arm of said crank and at its other end to a vehicle.

1,010,786. Wheel. Edward J. Nelson, Alliance, and Frank H. Lang, Havelock, Neb., assignors of fifty-two one-hundredths to Vaclav F. Hofmann, Havelock, Neb. Filed Apr. 13, 1911. Serial No. 620,941.

A wheel comprising a hub, an inflatable tube carried by the hub, a rim having a continuous outstanding flange on its inner periphery, clips straddling said flange and adjustable thereon, spokes pivotally connected to the clips and having a sliding engagement with the hub, and shoes carried by the inner ends of the spokes, said shoes being in engagement with the aforesaid tube.

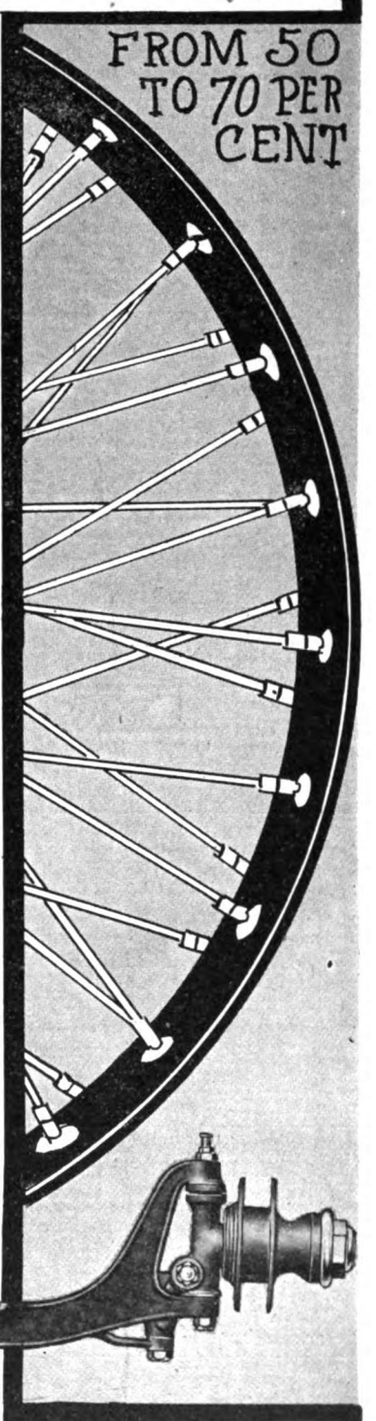
McCue Axles are so constructed as to carry either wire wheels or wooden wheels on the same spindle.

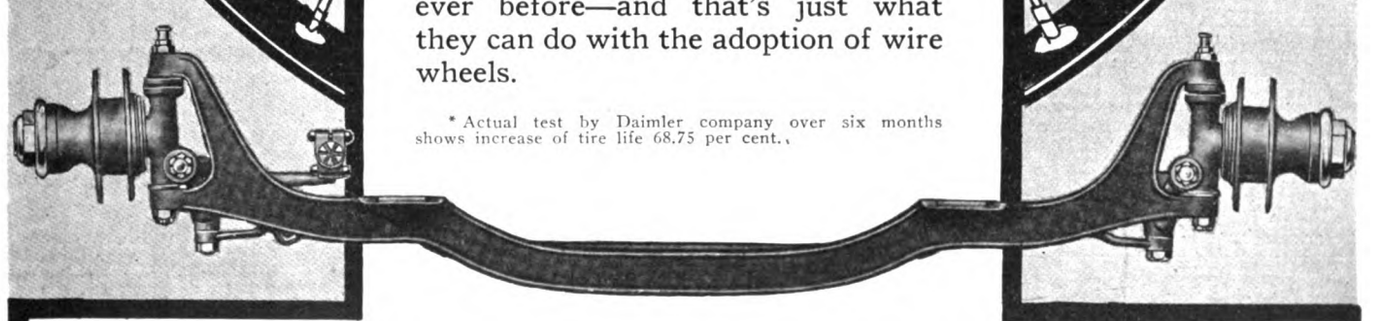
In preparation for the turn to wire wheels, The McCue Company has done everything it could do to make the change as easy as possible.

For instance, McCue Axles may be had which will admit of either wire or wooden wheels on the same spindle. This makes it easy for the manufacturer to offer wire wheels as optional equipment without disturbing his design whatsoever.

70% MORE TIRE MILES



WIRE McCUE WHEELS



No one development since the birth of the industry has meant so much in the increase of tire life as the perfection of wire wheels.

The fact that they radiate the excess of heat produced by driving and that they absorb road shocks by their "springiness," thereby prolonging tire life as much as 70 per cent.* makes wire wheels assured as general equipment on up-to-date cars.

Dealers know that they can sell more cars if they can guarantee two or three thousand more miles than ever before—and that's just what they can do with the adoption of wire wheels.

* Actual test by Daimler company over six months shows increase of tire life 68.75 per cent.

McCue Axles Are Dependable Axles

THE McCUE COMPANY, Buffalo, New York

For Sale—Wants—Exchange

15 cents per line of six words, cash with order.
— In capitals, 25 cents per line —
A market place where Dealers, Jobbers and Manufacturers may buy, sell or trade second hand cars parts and appliances and secure help or situations at a nominal Cost

ONE new seven-passenger aluminum auto body complete with top; upholstering fine shape, color maroon. KNOWLTON WAREHOUSE CO., 93 Perry St., Buffalo, N. Y.

FOR SALE—Overhauled 5-seated Maxwell; new tires; extra tires; two inner tubes; $350. GEO. J. FRITZ, 3508A Wyoming St., St. Louis, Mo.

BUICK roadster, model 26, 1911; fully equipped; fine car for physician; practically new and in splendid condition; cost $1,100; will sell for $650. BOX 341, Cardington, Ohio.

LET us put a good top on your runabout for $14 or touring car for $27; satisfaction guaranteed. BISON TRIMMING CO., Buffalo, N. Y.

SEVEN passenger car, three months in use, 1911. $2,500. H. CLARK, 292 East 135th St., New York City.

I WILL BUY FOR CASH automobile tires, accessories and supplies in any quantity. E. C. CORNWELL, 369 Normal Ave., Buffalo, N. Y.

FOR SALE—Light delivery runabout, $75. HATHORN, rear 98 Joiner St., Rochester, N. Y.

SITUATION WANTED—Young man, 27, single, industrious, desires position as office assistant with automobile concern; exceptional references. JOSEPH COHEN, 200 Orchard St., New York City.

FORD OWNERS, improve the appearance of your Fore Door Touring Car or Torpedo Runabout 50%. Send postal for information. LINDELL AUTO SALES CO., 3444 Lindell Ave., St. Louis, Mo.

FOR SALE—6-cylinder 60 H. P. Palmer-Singer 5-passenger touring, 4 speeds, 138 wheelbase, fully equipped, top, glass, Warner instrument, extra new casings, tubes, etc. Only run 4,500 miles and not a scratch on body. Car is in perfect condition. Cost $3,900, will sell for $1,700 if taken soon. BOX 13, Columbus, Neb.

AGENTS WANTED — To handle the $1000 G. J. G. "Junior," racy, classy and specially designed chaseabout with 104-inch wheelbase, with a real 26 H. P. motor, Bosch magneto, Dorian remountable rims with 32 x 3½ tires, at a price of $1,000, which is a money-maker for the sales agent. Write for literature and discounts to G. J. G. MOTOR CAR COMPANY, White Plains, N. Y.

WANTED—Position as demonstrator and salesman, or chauffeur; am experienced. E. C. A. FELZIEN, Heartwell, Neb.

PISTON RINGS. ALL SIZES. FITTING BY EXPERTS FREE. THIRTY CENTS EACH. MERRITT COMPANY, 409 East 31st St., NEW YORK. 'Phone 585 Madison Square.

FOR SALE—Chase delivery automobile, panel top with rear doors; capacity 1,500 lbs.; perfect condition; just used short time; speedometer, windshield, electric horn, chains, tools, lamps, etc., complete; cost $1,200; will sell for $600. KELLOGG, 119 N. Main St., Rockford, Ill.

SCHACHT RUNABOUT — First-class condition; cheap. DUHLMEIER BROS., Wade and McLean Ave., Cincinnati, Ohio.

WILL SELL Special Racing Roadster exceptionally cheap. Has Rutenber 30 H. P. motor, unit power plant, with selective 3-speed transmission and Raybestos multiple disk clutch. Full floating rear axle, 20-gallon gasolene tank at rear, tires in good condition, Bosch dual magneto, and windshield. WESTERN MOTOR CO., Marion, nd.

WHEELS, WHEELS, WHEELS—We have just bought a carload in sizes such as 34 x 4, 34 x 3½, 36 x 4, 36 x 4½, 36 x 5, 36 x 5½, 38 x 4½, 38 x 5½. These wheels are all equipped with rim, some with hubs, some without. Will sell any size in order to make room for other stock, at $2.50 each. We also have wheels of all sizes for Thomas cars. We carry in stock rims and parts for all make of rims. KASTNER TIRE & RIM CO., 2112 Michigan Ave., Chicago, Ill.

AUTOMOBILES—A. C. C. A. Prices Talk! Every make. Every model. Hundreds runabouts, racy roadsters, five-seven passenger touring cars. $50 up. Guaranteed five years. Shipped Freight Prepaid! Weed Chains

The Great Anti-Skid DEVICE

Nine-tenths of all accidents to automobiles are caused by skidding or slipping.

Either you skid into the "other fellow" or the "other fellow" skids into you.

No matter how careful a driver you may be, you cannot prevent skidding or slipping on wet, muddy snow-covered roads or on icy, slippery greasy pavements unless you equip your car with Weed Chains.

Cannot Injure Tires

Because They Creep

An absolute necessity on both rear wheels and if you want to know what real steering steadiness means put them on the front wheels too.

For your own safety—for the safety of the public, fully equip your car with Weed Chains. Make it your business to get a set today.

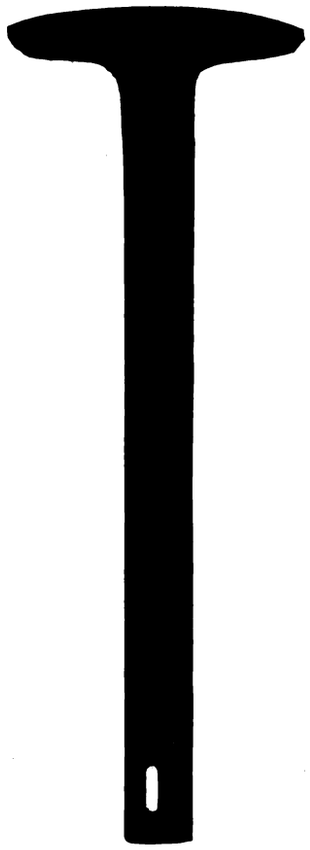
WHITNEY

The Greatest Mileage



can only be obtained by the use of materials properly hardened which will resist the most wear. Through our untiring efforts to produce nothing but the best and our years of experience in chain making, "Whitney" Chains have gained a remarkable reputation for their strength, accuracy, wearing qualities and ease of repair.

The "Whitney" Cotter Detachable Chain is the most practical chain for motor trucks, because it can be taken apart at any link and lengthened, shortened or repaired without the use of any special tool. When making replacements insist on a "Whitney" and get acquainted with its merits.

Look for the Cotter Pins

THE WHITNEY MFG. CO., Hartford, Conn.

THINK THIS OVER very carefully and read it twice, if necessary.

Is there any part of an automobile engine, or any other gas engine, that is more important to its efficiency than a Valve?

Your engine leaves the factory running smoothly and sweetly—tuned up to its highest power. Perhaps the valves pit—warp - go out of shape—fail to hold compression. Then the power diminishes, and what can be more aggravating to the driver, who has known the fullness of the pulling power of his motor, than to have it grow less and less?

You cannot slight this part by putting in an inferior product—valves that will give trouble, or even break from inexperience in their manufacture—valves of unsuitable material, not suitably heat treated.

Too much is at stake, and a slight extra cost at the outset, which is the exception, may save you many times over a probable later expense.

This Company, with the experience of many years as a guarantee, will furnish you with properly made valves, of the materials best adapted to your requirements.

Not only QUALITY, but efficient SERVICE is a factor—surely there is a satisfaction in getting the kind of work you want—when you want it.

Mr. Automobilist:

Your tire maker is very anxious to impress upon you the importance of

Tires Inflated to the Right Pressure

He insists that this is tire economy and

Saves You Money

How do you know what pressure you have in your tires? A

SCHRADER
UNIVERSAL
Tire Pressure Gauge

(Trade Mark Registered in U. S. Patent Office)

(Patented March, 1898—Other Patents Pending)

will tell the exact pressure in your tires at any time, day or night, by simply holding this Gauge to your Valve for a second. Its recording sleeve remains in place, showing the exact pressure in the tire so that the Gauge can be taken anywhere and read, at night to the front of the car into the light of the lamps. After the pressure has been ascertained the Indicating Sleeve can be pushed back into the Gauge with your finger. No catches or snaps to operate or get out of order. This Gauge is 2½ inches long over all, short enough to apply easily to the smallest diameter of wheel and can easily be carried in the vest pocket or the change pocket of your trousers.

Price $1.00 Each

The New Twitchell
Positive Lock Stop
Gauge

Increases Mileage

Decreases Tire Expense

Accurate, Simple and Instantaneous

Insures Correct Tire Pressure

A Vest-Pocket Necessity for Every Motorist

IF Twitchell Gauges were not so accurate and reliable, there would not be so many of them sold.

An inaccurate tire gauge is like an inaccurate watch. Both are worse than useless. As good materials and as masterful workmanship are found in the Twitchell Gauge as in the most delicate, scientific instruments. Therein lies the motorist's protection.

In the course of manufacture, this gauge undergoes four different inspections. It is absolutely simple. Unlike other gauges, it contains no rubber washers to wear out or deteriorate. Neither are its internal or external parts subjected to friction or wear.

Correct pressure in all 4 tires is essential to the utmost tire efficiency—maximum mileage. Otherwise the brunt of the wear and tear of traction falls on your softest tire. You cannot determine a tire's pressure by guess work—you can with the Twitchell Gauge. It can be easily read day or night—the graduated bar remains at the pressure indicated till a slight pressure of the thumb on the extreme end of the ratchet side returns the register to zero. Made to carry in the vest pocket—only 3½ inches long.

Price $1.00 each

They Barred the Franklin Out

The Quaker City Motor Club of Philadelphia conducted an economy run for motor cars April 27, open to all pleasure cars with the exception of air-cooled cars.

What They Did

In the Quaker City contest, open only to water-cooled cars, first prize for economy was awarded to a two-passenger car that averaged 22.7 miles per gallon of gasoline.

What the Franklin Has Done

46.1 miles on one gallon of gasoline in the economy contest conducted by the Automobile Club of Buffalo.

87 miles on two gallons of gasoline in the economy run held by the Automobile Club of America.

The Motor Lamps with Distinctive Features

There are no other motor lamps on the market with the advantages of Solar Lamps. Solars are always exclusive in style and in quality. They are the strongest lamps as well as the most effective.

In no other lamps can you obtain the Solar Special Short Focus Lead Glass Lens Mirror Reflector—the patented system of double ray light projection which gives two distinct fields of light for town and country use—or the new and exclusive black finish with a metallic lustre which is unaffected by heat or moisture. All of these features are exclusively "Solar."

Do not equip your car or specify equipment to the maker until you have seen all of the Solar advantages. See Solars at any live dealer's or write for the catalog.

Solars are made in all styles for oil, electricity, gas and in combinations.

K·D

The Motor With the Sliding Crescent Valve

KNIGHT-DAVIDSON

1896 — 1912

The CRESCENT valve of the K-D Motor, fitting around the stationary piston wall affords a larger port area than any other poppet or slide valve on the market. It is simpler and, consequently, better than any other valve construction known and is here offered to discriminating manufacturers, not as an experiment, but as a tried, tested and proved mechanical advance. The K-D motor is simple, silent, cools rapidly, has the simplest oiling system known, will not carbonize. Last and most important, will give on a given quantity of fuel more power, speed and endurance, unit for unit, than any other engine on any type of an automobile. We want to present some facts to interested manufacturers.

KNIGHT-DAVIDSON COMPANY, Boston, Mass.

KNIGHT-DAVIDSON

THE CENTURY

B & L CASTER FRONT AXLE

Makes a Big Winner in Philadelphia

Our Philadelphia Agent writes it is a Great Success.

A. S. BURNELL, President and General Manager,
1346 Michigan Avenue, Chicago, Ill.

Dear Sirs:—The axle is a great success, is running fine. Have made several demonstrations and every one says it's the only front axle that ought to be allowed to go on the automobile, for safety, easy steering and perfect control. Will sell the majority of those I have demonstrated for. Enclosed you will find order for one axle to go on a Studebaker car, 1908 model, more orders will follow later. We will equip at least one thousand cars this year. Our new garage will be at 1907 N. 23d St., after March 12th. Circulars received all O. K., thanks for same. Rush the order for axle, as every one on a car will sell several more.

Yours very truly, H. SCHROEDER,
President and General Manager Lake Schroeder Auto Exchange.

Philadelphia, Pa., 1418 Blavis St.

AGENTS WANTED for all cities in the United States to put the B & L Caster Front Axle on old cars. Exclusive territory given to good men. Our axle when on a car proves that it is the only safe axle made. In buying a new car demand that it be equipped with the B & L Caster Axle. Write for Agency Proposition. Address:

SHAWMUT TIRES

SOLD EVERYWHERE SHAWMUT TIRE CO., Boston, Mass.

Digitized by Google

He Who Gives Most Will Get Most

That's the sole reason why No-Rim-Cut tires outsell all other tires.

That's why the sales have trebled in the past 12 months.

That's why these tires are used today on some 200,000 cars.

Just because we gave so much that average tire bills have been cut in two. And men have found it out.

The Tire That Became the King

This is the tire which stands today as Tiredom's undisputed king.

A tire which is now in its 13th year. But ten of those years were spent in silent obscurity, while the tire was being perfected.

Then suddenly this new type became the sensation. Users told others about it, and the others told others. The fame of this tire spread like wildfire.

In the past two years the demand for this tire has increased by 500 per cent.

Now 1,100,000 have gone into use. Now, with a capacity of 3,800 tires daily, we run night and day, with three shifts of men, to keep anywhere near up with the calls for this tire.

Reason No. 1
Finality in Tires

One reason lies in the perfect construction.

We built a testing machine, where four tires at a time are constantly worn out under all road conditions.

There we tested some 200 fabrics, some 40 formulas for treads. There we compared every method and material, and compared rival tires with our own.

There, by metered mileage, we proved beyond question how best to build a tire. By ceaseless selection we brought them close to finality.

Reason No. 2
Rim-Cutting Ended

Then we invented this way to end rim-cutting.

We made a tire which doesn't hook to the rim flanges. So your removable flanges can be set to curve outward, not inward as with old-type tires.

The tire when wholly or partly deflated rests on a rounded edge, and rim-cutting is made impossible.

We did this by making an unstretchable tire base—by vulcanizing into the tire base six flat bands of 126 braided wires.

And this method—controlled by our patents—forms the only practical way to make a tire of this type.

Statistics show that avoidance of rim-cutting saves 23 per cent of the ruin to tires.

Reason No. 3
10% Oversize

Then we made these tires—No-Rim-Cut tires—10 per cent over the rated size, to save the blow-outs due to overloading.

That means 10 per cent more air—10 per cent added carrying capacity. And that, with the average car, adds 25 per cent to the tire mileage.

No-Rim-Cut and oversize, for armies of motorists, have cut tire bills right in two.

Reason No. 4
8½% Profit

Our multiplied sales, plus our modern equipment, gradually cut the cost of production. Then we pared our profits down to the minimum, to give you the utmost one could give for the money.

Last year our profit on No-Rim-Cut tires averaged 8½ per cent. Below that, in tire making, no maker can go.

For all these reasons, 200,000 motorists have come to No-Rim-Cut tires. And you will join them when you know the facts.

Our 1912 Tire Book—based on 13 years of tire making—is filled with facts you should know. Ask us to mail it to you.

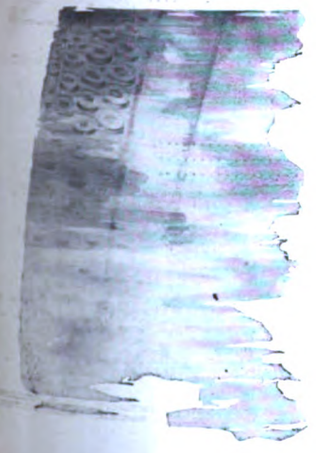
A Trade Paper Giving the World's Motor News

Vol. XXXII
No. 2

New York, July 4, 1912

Ten cents a copy
Two dollars a year



WE have made a profound impression with our widely advertised and exceptional guarantees on these tires.

Because our guarantees are just the kind to appeal to the motorist who has had the average sort of experience with tire service costs and adjustments.

If you could sit here at headquarters and watch the demand grow you would hesitate not a day in stocking

PENNSYLVANIA VACUUM CUP TIRES

With each casing goes a printed definite guarantee of 4000 miles actual service, stipulating the fairest terms your customer could desire.

The additional guarantee that a car equipped with Vacuum Cup Tires will not skid on wet or greasy pavements or the tires may be returned at full purchase price, is also a powerful incentive.

In short, there's too strong and definite a demand for Vacuum Cups for any live dealer to let it go by him.

The thing to do is stock them, and the time to stock them NOW.

The First HENDERSON Birthday Car Was "Hartford Equipped"

CABLE ADDRESS "HENDERSON"

HENDERSON MOTOR CAR CO.
INDIANAPOLIS, U.S.A.

May 29, 1912.

Hartford Auto Parts Co.,
Hartford, Conn.

Attention of Mr. D. F. Kalish.

My dear Mr. Kalish:

I wish to thank you for your prompt attention in getting this material out for us. As you will see by the trade papers, it was vitally essential that we have these parts out, because today, the 29th of May, is what may be called the Henderson "Birthday", inasmuch as our first car was placed on exhibition in the Claypool Hotel lobby, and I am pleased to say, it contains a Hartford clutch. I trust that the rest of the clutches will be as satisfactory as the one we now have.

Yours very truly,
THE HENDERSON MOTOR CAR CO.

Charles S. Rieker
Chief Engineer.

Almost unnecessary to state that the balance of the Henderson output will carry Hartford clutches.

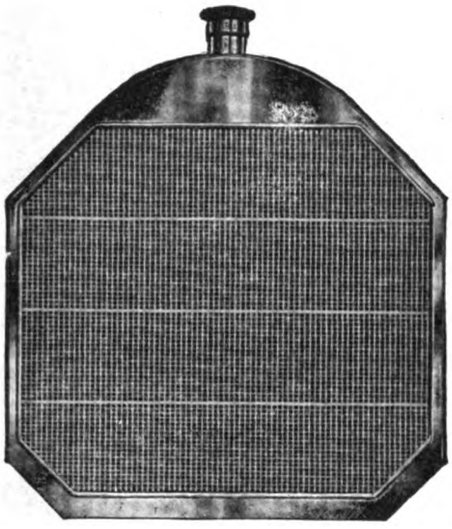
"Made in the Largest Axle Factory in the World"

Axle Talk—No. IX

The positive lock nut—a SHELDON detail feature—is a large factor in safety. Especial attention is called to it just to emphasize the attention paid here to minor construction details, which in the aggregate means all round strength —and in axle strength lies safety.

SHELDON Axles have grown out of the crucible of experience into a science based on precise knowledge.

In the making, a physical laboratory, a chemical laboratory, an engineering staff of more than ordinary size and worth, a plant of unrivaled magnitude, all work along pre-determined lines.



SHELDON Axles are resultant products—not haphazard "may-be-goods" but by test and comparison "The Best in The World."

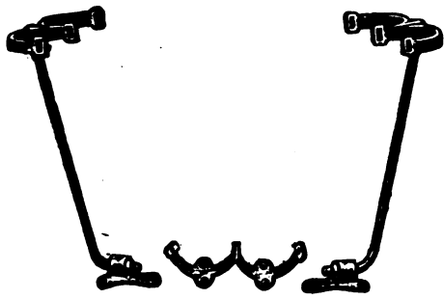
The Mayo—the radiator thoroughbred

A MAYO RADIATOR

on any car is insurance of trouble freedom so far as this part is concerned.

¶ If these radiators had ever developed weak points we would know it for we have been building them long enough to "get the answer."

¶ We have proved, by the large and ever growing demand, that these radiators present a maximum of cooling surface, through correct design, and strength that even defies rough treatment, through right materials and construction.



¶ Insist on Mayo Radiators.

"Torpedo" Tire and Demountable Rim Holders

Designed especially for use on Torpedo body or Fore-door cars. Set consists of two strong arms firmly bolted to running board and permitting of sufficient adjustment to accommodate two tires or demountable rims, of standard sizes, 4 inch or smaller. Made of solid Brass and guaranteed to give perfect satisfaction.

Finish: Furnished in Hard Rubber Black Enamel finish, and full Polished Brass.

	Brass	Black
Price, complete with Straps...	$4.00	$3.00

A dozen other styles and sizes in stock. See catalog.

Our 1912 Catalog, which is held as a book of reference by manufacturers, dealers and automobile owners, will be mailed on request. Circulation limited to 100,000 copies.

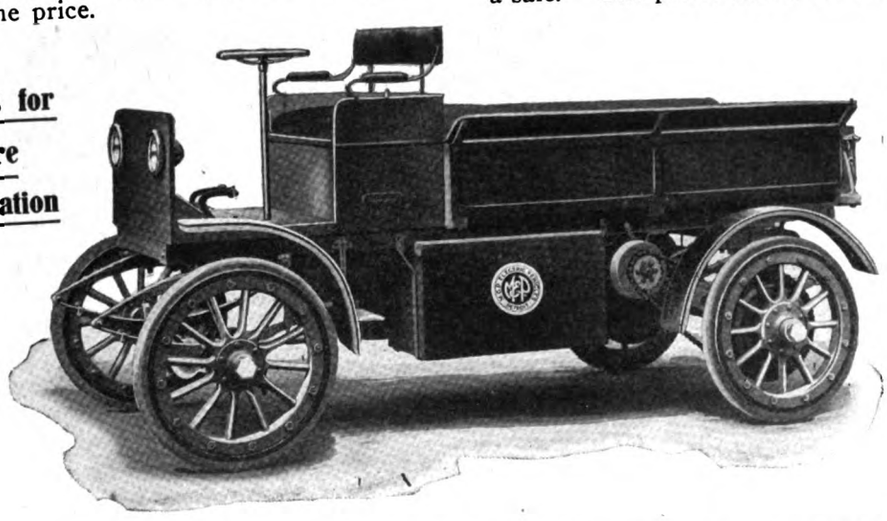
The M&P 1000 lb. Truck sells for $1500

WE ARE the pioneers in the production of a high-grade electric truck that will successfully compete with others of its type that sell as high as $2200.

This will be welcome news to that great body of merchants who have, heretofore, been forced to be content with a gasoline truck selling at, or about, the same figure, for until we made this radical advance, the electric truck was beyond the means of the average dealer in merchandise.

That the M & P Electric Truck for $1500 is low priced does not presuppose any lack of quality in workmanship, construction or material.



We positively guarantee this truck to be standard in every detail, sturdily built, capable of withstanding more abuse and rough treatment than any gasoline truck at twice the price.

We claim for it long life, better service, cheaper cost of operation than that comprehended by a gasoline truck of twice the price.

The M & P Electric was built before the selling price was decided on. We first made a truck as good as we could and then placed the price within reason, preferring quantity sales and small profits rather than limited sales and unwarranted profit.

We want to get dealers interested in this proposition. It is ideal in every particular. The truck has already proved itself and its popularity indicates small sales resistance. A demonstration usually means a sale. The prices are as follows:

Ask us for more information

Chassis $1450

Express Body $1500

Enclosed Body $1600

"The Horn that's Made for the Discriminating"

TUTO HORN

THE TWO TONE HORN

Automatic in Operation.

CONSIDER the service value of all the warning signal devices now on the market.

¶ What can you do in a case of emergency?

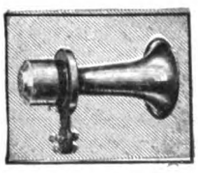
¶ To begin with, the low note horn is absolutely necessary as partial equipment on every motor car, for 90% of the warning signal notes need not be extremely loud to get the right-of-way. That is why the inefficient bulb horn is retained by car owners and manufacturers who have adopted the inflexible-loud-note horn for emergency purposes.

¶ This is a duplication of warning signal mechanisms and of operating means—a bulb and a button, separated and requiring an extended movement of the hand to go from the one to the other.

¶ If the bulb is used for ordinary signalling, its inadequate note makes it necessary to go to the louder signal, and when at close range.

¶ The bulb and button being separated, require a movement of the hand and the concentration of thought, right at a critical moment, when life, limb or property is in danger.

¶ Thus, the supplementing of one inadequate signal with another one-purpose emergency signal, is now acknowledged the most inefficient and ineffective combination.



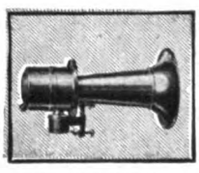
¶ All of these signalling troubles are overcome by the TUTO Horn, which does all of the signalling of the car by producing a low abrupt service signal for use in place of the bulb horn, and a loud signal for emergencies or where the milder note proves ineffective. The going from the low note to the loud note is done by merely increasing the pressure on the one button—a simple, rapid and safe operation which does not require extended movement of the hand.

¶ This increased pressure on the TUTO push button is unconsciously obtained by the gripping of the steering wheel at the approach of danger (button already partially depressed for the low note), then going clear down so as to get the loud emergency signal.

¶ There is no hesitancy, no chance for confusion and the car is kept in full control at all times.

¶ This automatic action is not obtainable in any other warning device (patented) and is worth many times the price of the TUTO Horn.

¶ Do not fail to specify the TUTO if you desire the best in warning signal service.



TUTO Horn, $25.00

THE NATIONAL STARTER

NO Gas Air Electricity or Springs — BUT A Resistance Reducing Application of Simple Mechanical Principles — It Cannot Fail You —

It is but logical and right that starting the engine should be a mechanical operation—just as braking, using the clutch or changing speed is mechanical.

Gas, electricity or compressed air are never used in these operations—they're all too uncertain.

The National Starter is just as efficient and simple as the brake installation and it cannot fail under any condition.

The illustration tells the story.

This starter is not an experiment being tried out in a "half baked" state on credulous car owners.

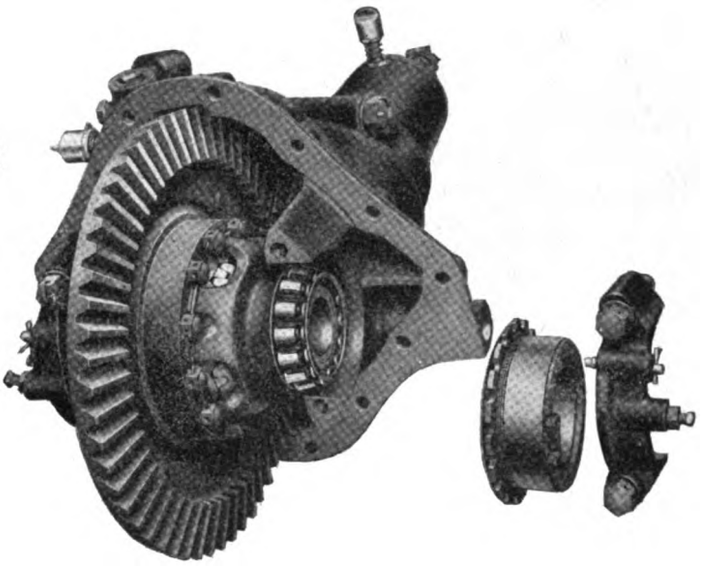
We have subjected it to tests covering a long period of time and we guarantee it to—

Outlast any car on which it is installed.

Operate one thousand times out of one thousand.

Stand rough treatment and abuse.

Now, Mr. Dealer, if you are handling one or more of the many complicated self starting devices that depend upon valves, tubes, springs, wires, pumps, magnetos, gas tanks, etc., then consider this rational, purely mechanical starter.



It is the coming solution to the self cranking problem —in fact, it's not coming—it's here.

There is still plenty of unoccupied territory—write and get your share of it, but do it to-day.

Power Transmitting Unit
Timken-Detroit Rear Axle

The Gear with the Polished Teeth

On the manager's desk lay a gear with teeth that shone like silver. 'Twas the first thing that caught the motor car engineer's eye when he called at the Timken-Detroit plant. The first question that he asked concerned the gear with the polished teeth.

TIMKEN-DETROIT GEAR-GRINDING PROCESS

It was explained to this engineer for one of the highest grade cars that Timken-Detroit gears are ground by a Timken-patented process which corrects all the microscopic inequalities left by even the finest gear cutters.

He was taken out into the factory and shown the special Timken-built machines at work. He saw at a glance that the theory of perfect master gear and master pinion controlling the gears to be ground was sound.

Next day he brought the production manager of his plant to see the wonderfully simple and efficient machines.

The Proof Demanded

The process looked right, but they asked for proof of results.

"Send us," we said, "some of your gears that have failed to pass your inspection. Mark them secretly and, after they're ground and returned, mix them with others and send them through your testing department again."

This was done. Ten gears that had failed to pass were sent us to grind. They were put through the Timken-Detroit gear grinding process and returned.

Every one of those gears passed inspection.

The inspector was asked to pick out the ten best gears in the lot. He picked out the ten that we ground.

The Result

Today the driving and pinion gears in each of their cars are ground by the Timken-Detroit process.

The Company has gained because the process corrects faults that formerly scrapped many gears.

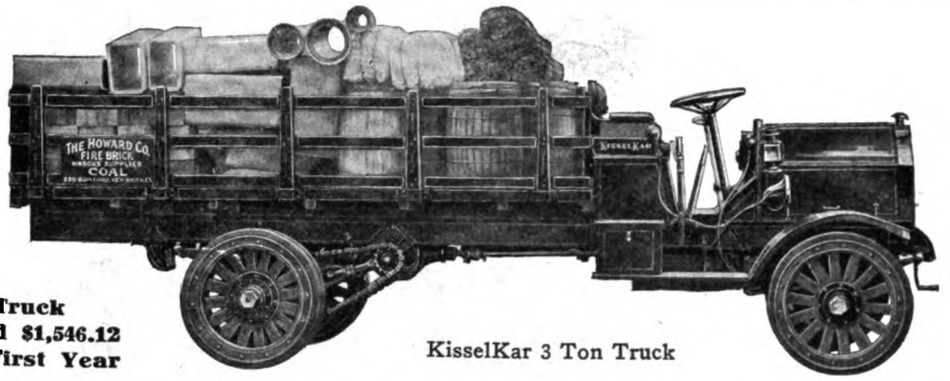
The car owners have gained because all the gears are now perfect. Friction has been reduced and noise practically eliminated.

Applied to Timken-Detroit Axles

Every gear in the Timken-Detroit Axle is ground by this special process.

Timken-Detroit Axles are the only axles equipped with gears ground by a process that produces the results which so thoroughly convinced this engineer and this production manager. (Names will be given on application.)

There are many other true stories of superiority in Timken-Detroit manufacture—tales as interesting and important as the story of the Gear with the Polished Teeth.



The Timken-Detroit Axle Company

Detroit, Michigan, U. S. A.

The only axle manufacturer licensed to make axles equipped with the famous Timken Roller Bearings

This Truck Saved $1,546.12 the First Year

KisselKar 3 Ton Truck

Saved $1,546.12 First Year

THE purchase price of this four-ton truck, owned and operated by the Howard Company, of New Haven, Conn., plus interest, depreciation, overhauling, fuel and driver's salary for one year, amounted to $5,921.88.

It replaced three double trucking teams. The cost of the horses, wagons and harnesses, plus interest, maintenance and drivers' salaries for one year amounted to $7,468.00 A balance in favor of the truck of $1,546.12—the first year.

A Kissel truck is your logical selection because it is the truck of surest economy and slowest depreciation. It is strong, simple and silent. It carries 50 per cent. overload without harm. It rides easiest. It consumes the least fuel.

Note these striking KisselKar merits: its wonderful engine—its lock on the differential which equalizes power between rear wheels, when, without it, a slipping wheel would absorb all the power—its fourth geared up speed which saves the engine when driving empty and makes fast time judicious when haste is necessary.

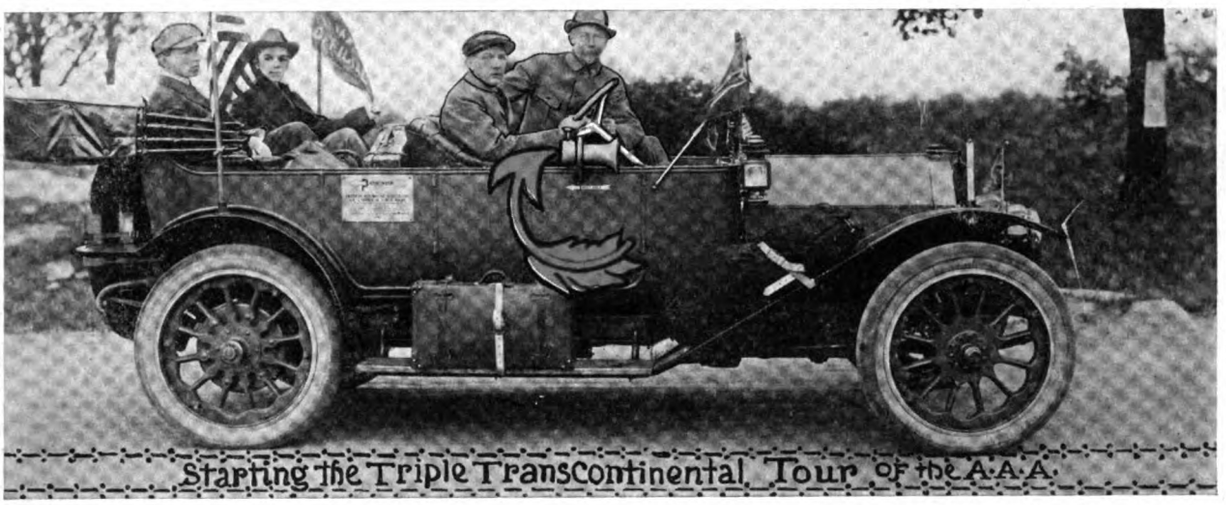
At the disposal of KisselKar owners is the unrivaled KisselKar service, consisting of completely equipped service buildings at leading centers, where the mechanical end of motor trucks is taken off your hands.

KISSELKAR TRUCKS

1½ to 2, 3, 4, 5 Ton Trucks, Delivery Wagons, Etc.

Write and tell us how many horses you use, how many trips they make per day, single or in teams, the average number of stops per load, carrying capacity of your equipment, average daily distance covered, cost of drivers and aids, general nature of the highways traveled.

Do this and we will tell you how motor haulage may be most advantageously used in your business.



Your copy of the new catalog is ready. Send for it.

Starting the Triple Transcontinental Tour of the A.A.A.

A. L. Westgard, official Pathfinder and Pilot of the American Automobile Association, has equipped the triple transcontinental car with

THE LONG HORN

The reasons for using the Long Horn on this important official trip may be summed up very briefly in the following statement of facts.

Because the Long Horn never fails to work. If you can push the button the Long Horn will respond with a warning note. There are no parts to give out. No wires to break. No friction pulley to slip. No bulb to rot or crack. No motor to fail to work. No cost of upkeep.

The Long Horn is a perfect and positive mechanically operated gear driven horn that can never fail to issue its warning note.

The gear driven mechanism depends only on the pressure of hand and elbow for its source of power.

There is no transmission of power from engine or from a battery or generator nor is there any delicate mechanism to get out of order.

And there is no maintenance expense.

Dealers will find the Long Horn a ready seller.

The fact that Mr. Westgard is using the Long Horn is an argument in favor of its sale.

Write today for unoccupied territory.

Some One Always Leads the Procession.

IN AUTOMOBILE TIRES,

THE DAHL PUNCTURELESS TIRE LEADS

The **DAHL PUNCTURELESS** is no new sensation: it has been on the market for three years. It has been tried out and has been found to be "entirely satisfactory" by thousands of users. It tells its own story and this is the story it tells.

A soft, resilient, rubber-like product, moulded into shape to fit your casings and, when compressed in the casings, makes a very resilient cushion filler that replaces the inner tube. Your car, when equipped with the **DAHL PUNCTURELESS,** rides like air but has none of the disagreeable disadvantages of the air tire.

No blow-outs, no punctures, no worry, no waste of time by the roadside, no flat tires, no accidents caused by punctures or blow-outs.

With the **DAHL PUNCTURELESS,** when you start on your journey, you have that feeling of safety and freedom from worry that you never can have when riding on air tubes.

If you have ever noticed you will have observed that your casings are seldom discarded because worn out: they are generally thrown away when about half worn out because they are blown and cannot be repaired.

DAHL PUNCTURELESS saves its cost to you in a very short time by the extra mileage you get on your casings. They do not blow out with the **DAHL PUNCTURELESS** and you do not have to replace them as you do the blown-out tires.

Beware of Imitations

There is no other product on the market like the **DAHL PUNCTURELESS.** Don't allow yourself to be misled or fooled by any fancy advertisements of other fillers, imitations of the **DAHL PUNCTURELESS.**

INVESTIGATE; your investigation will disclose that no other product in the world can begin to touch the **DAHL PUNCTURELESS.**

The general public has set the seal of approval on the **DAHL PUNCTURELESS;** wise old party is Old General Public; when his approval has been secured it is a sufficient recommend . .

The **DAHL PUNCTURELESS** made its first appearance three years ago and our sales have greatly increased each year. Today we cannot supply our demand. We put our money into the quality of our goods. No need for us to spread our money on billboards and in printer's ink: the quality is what talks; our customers all like the **DAHL PUNCTURELESS** and want more of them and recommend them to their friends. MERIT WINS every time and that is why **DAHL PUNCTURELESS** wins. The **DAHL PUNCTURELESS FILLER** has come to stay.

Manufacturers, Take Notice

If your cars are not built to be equipped with some first class filler product like the **DAHL PUNCTURELESS,** you have got to build them right. Any well built car will carry **DAHL PUNCTURELESS** equally as good or better than it will carry air; and any car that will not carry **DAHL PUNCTURELESS** is not a well built car.

Customers, Take Notice

If any manufacturer tells you not to equip your car with **DAHL PUNCTURELESS,** do not buy his car, because if you do you will get a bunch of junk instead of a car. You want an automobile.

The **DAHL PUNCTURELESS** is represented in all large cities in the United States. If you want full information, write to or call on any of the following representatives.

ALABAMA—H. W. Roloson, 512 So. 20th St., Birmingham, Ala.

1/4 MILLION

EXHAUST TUBES IN TWELVE MONTHS

We made this enormous quantity because we received orders for them. We received orders for them because we can make them better, cheaper and quicker than any one else.

We make them better because we have the most up-to-date machinery and employ only expert workmen.

We make them cheaper because we make our own tubing and make so many.

We make them quicker because we know how to make them and do not fuss, fret or fume if the job is new or a "sticker."

Our tubes are strong, accurate to dimensions and very light in weight.

It is not foolish to make your own tubes, but it's futile, especially when you can get what you want without wandering.

The Truth Regarding The Gas Tank Patents

The U. S. Court for the Northern District of Illinois has, on final hearing, re-affirmed its previous decision in the gas tank patent case.

The case will now be appealed to the U. S. Circuit Court of Appeals, 7th District, and a decision which will settle the controversy is expected in the fall.

Until a final decision is reached, the dealer is advised to "sit tight."

Meanwhile, these facts may be of interest:

Have the Gas Tank Patents Expired?

Decided "Yes"

U. S. Court, Northern Dist., Illinois.

Decided "No"

U. S. Circuit Court of Appeals, 6th.
U. S. Court, Eastern Dist., Michigan.
U. S. Court, Indiana.
U. S. Court, Eastern Dist., Missouri.
U. S. Court, Southern Dist., California.
U. S. Court, Western Dist., Washington.
U. C. Court, Colorado.
U. S. Court, Western Dist., Texas.

Can Other Firms Re-fill Prest-O-Lite Tanks?

Decided "Yes"

U. S. Court, Northern Dist., Illinois.

Decided "No"

U. S. Court, Eastern Dist., Wisconsin.
U. S. Court, Western Dist., New York.
U. S. Court, Indiana.
U. S. Court, Northern Dist., Texas.
U. S. Court, Eastern Dist., Michigan.
U. S. Court, Eastern Dist., Missouri.
U. S. Court, Southern Dist., California.
U. S. Court, Western Dist., Washington.
U. S. Court, Colorado.
U. S. Court, Western Dist., Texas.

One Case Already Decided by Higher Court

The decision in the U. S. Court for the Eastern District of Michigan, favoring The Prest-O-Lite Co., has already been affirmed on appeal by the U. S. Circuit Court of Appeals, 6th Circuit.

Appeal in the case just decided at Chicago is being taken to the U. S. Circuit Court of Appeals, 7th Circuit.

We wish merely to emphasize this:

Until this appeal has been decided by the higher courts, the questions involved in the gas tank patent suits are not SETTLED, even as against the defendent in this one case.

The Prest-O-Lite Co., Indianapolis, Ind.

Charging Stations and Branches in All Principal Cities.

Digitized by Google

Regardless of the Final Decision on Gas Tank Patents, No Dealer Can Afford to Overlook These Points:

1st—Every concern that has tried to win agents and customers away from Prest-O-Lite has failed to do so, and ALL except those involved in the present law suits have gone out of business.

2nd—In each and every case, where the gas tank maker quit the business, the dealers have "held the sack" on worthless tanks that could not be re-filled.

3rd—Every company, past or present, that has claimed "more gas and better gas than Prest-O-Lite" has failed to make good the claim.

4th—Every company, past or present, that has promised an adequate exchange service to compete with Prest-O-Lite, has fallen down.

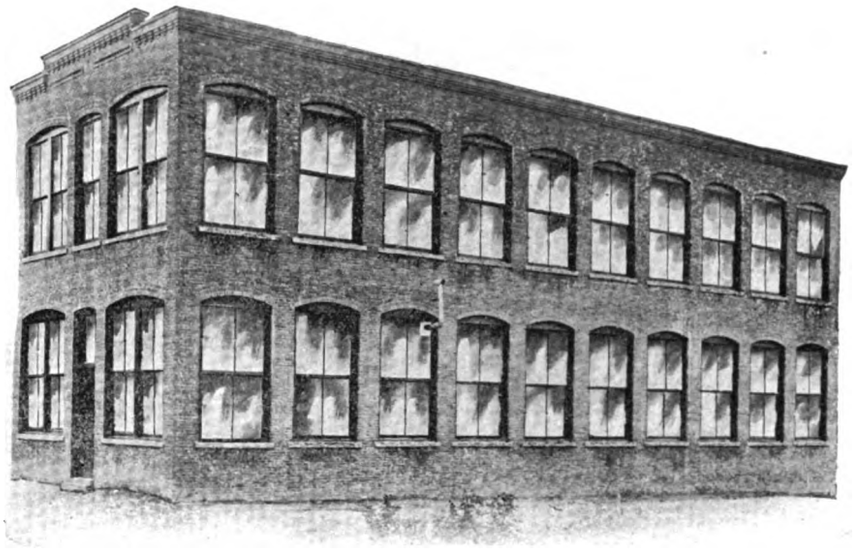
5th—Prest-O-Lite is, and will continue to be (no matter how the patent cases finally go)

The ONLY gas tank backed by adequate exchange service.

The ONLY gas tank that motorists and the vast majority of dealers will have anything to do with.

The ONLY gas tank that a dealer can handle without risk of "holding the sack."

The ONLY gas tank that will pay the dealer the profit he has a right to expect.



Prest-O-Lite has always MADE money for dealers.
Imitations have always LOST money for dealers.

The Prest-O-Lite Co., Indianapolis, Ind.

Exchange Agencies EVERYWHERE.

Is Your Name Frankenstein?

In Shelley's weird story "Frankenstein" is an inventor who instills life into a monster of his own manufacture. For a time he employed this mechanical creation to his own ends but later the automaton became the *master* — with terrifying results.

Be the *master* when it comes down to equipping your car with a speedometer. Don't accept an inferior one that will cause you everlasting trouble.

You can't go wrong if you insist on the speedometer used on the greatest number. It must be the best.

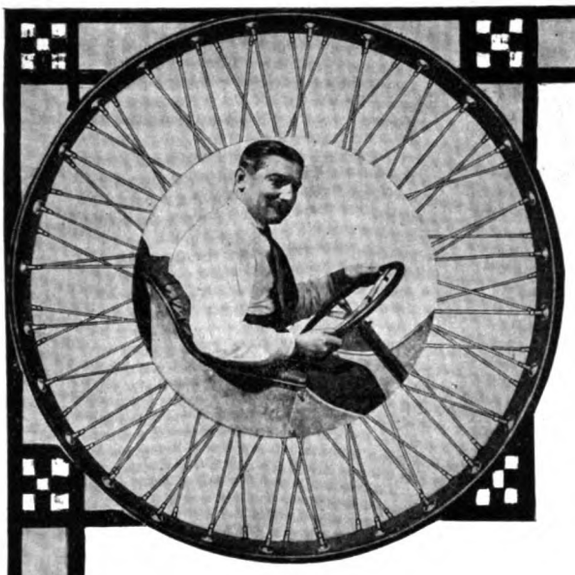
Speedometers that cost more than the Stewart are priced *high*, not because they are *better*, but only because they are *fewer*. The extra price doesn't represent *value*. It only means a *smaller* output.

The overhead charge borne by each Stewart Speedometer is *one-tenth* as big as that on any other. The divisor is that much larger. The Stewart's on *four* cars out of five. Others charge *more* because they make *less*.

The Stewart Speedometer *can't* be better—it *can't* be bettered.

Magnetic principle — jewel bearings — wearing parts hardened and polished — open dial — large figures, easily read — absolutely accurate; 100,000-mile season odometer — 100-mile trip register, can be reset to any tenth of a mile. Guaranteed for five years. Strongest flexible shaft—drop forged swivel joint—noiseless gears.

"ALWAYS ON THE JOB."



Speedometers, $15 to $30
Clock Combinations, $45 to $70

French "Grand Prix" over famous Dieppe Course won on wire wheels.

Thirty-six cars out of forty-eight starters wire wheel equipped.

Only six of the forty-eight cars used wooden wheels, six others using steel wheels.

Boillot, champion road driver of France, in a Peugeot car, mounted on WIRE WHEELS, won the French Classic over the Dieppe Course last week.

The remarkable preponderance of wire wheels on the cars in this race shows conclusively that there is no longer any question of the future of wire wheels. Out of a field of 48 starters only six cars were equipped with wooden wheels.

Cable reports of the performance of the cars in the race are unanimous in the statement that both De Palma and Bruce Brown, who shifted from wire wheels to wooden wheels the night before the race, lost a great deal of time because of tire trouble.

70% MORE TIRE MILES

WIRE McCUE WHEELS

W. F. Bradley, Motor Age representative in France, says in one part of his story, speaking of Bruce Brown —"But the American soon ran into tire troubles of which Boillot had none."

The Automobile, in speaking of the same race, says: "In Europe at least there can be no doubt of the favor of wire wheels for racing and for ordinary service as well."

The McCue Company is the foremost American manufacturer that is ready to meet the demands for wire wheels in this country.

McCue axles are so constructed as to admit of the use of wire wheels or wooden wheels on the same spindle.

THE McCUE COMPANY, Buffalo, N. Y.

Blue Prints and Price List Mailed on Request.

The Billings & Spencer Co.
HARTFORD, CONN.

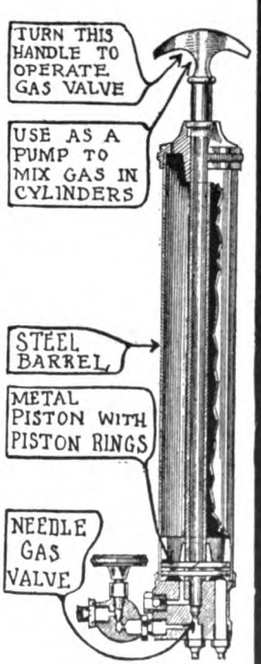
The Niagara Self-Starter

does not soot and foul your spark plugs, because it mixes the acetylene gas with pure air and forces this mixture into the cylinders of your engine.

Acetylene gas alone deposits soot thickly in your cylinders and upon your spark plugs. Avoid using starters which depend upon pure acetylene gas. Use only the Niagara Self Starter which mixes this gas with the proper proportion of pure air.

The compressor of the Niagara Starter, shown here, is made of seamless drawn steel tubing with a cast-iron piston and two cast-iron piston rings.

Self Starters using leather washers are inefficient because the leather washers wear out and rot quickly under the influence of acetylene.



The Niagara Self Starter is unaffected by acetylene gas and will last forever.

The Niagara Self Starter will start your car every time you get a spark in the cylinder.

The Niagara Self Starter never wears out.

e negotiations with the German the syndicate which has obtained to reproduce Mercedes pleasure this country was represented by H. F. Cuntz, the patent expert of the Automobile Board of Trade, which office he also filled in its successor, the Association of Licensed Automobile Manufacturers, of which Carples was traffic manager previous to his assumption of the general management of the Daimler Import Co. Cuntz returned from Germany on Tuesday last, but, like Carples, he will say nothing concerning the identity of those whom he represented on his mission to the Daimler factory and who will comprise the new company.

Atlas Engine Works in Receiver's Hands.

On the application of Frank H. Wheeler and George M. Schebler, who comprise the Wheeler & Schebler Co., of Indianapolis, Judge Weir, sitting in the Indiana Superior Court on Monday last, 1st inst., appointed Fred C. Gardner receiver for the Atlas Engine Works of that city, with authority to continue the business and complete the products now in process of manufacture. In their petition, Wheeler and Schebler, whose claim amounts to $2,387.50, allege that the Atlas company is in danger of insolvency.

In addition to motors of the standard type, the Atlas company, possessed of the only American license granted to an engine manufacturer, has been producing Knight sleeve valve engines, and also has been working on an engine of the Diesel type, all of which has required large outlay and working capital. Its embarrassment grows out of the temporary suspension of payments by its largest customer in the automobile industry, whose indebtedness aggregates $100,000, and who had further requested an indefinite suspension of deliveries of engines for which it had contracted quite heavily.

Locomobile Erecting a Truck Factory.

The Locomobile Co. of America has commenced work on a new building which will be devoted entirely to the production of its trucks. It is expected that the structure, which will adjoin the present plant in Bridgeport, Conn., will be completed within sixty days.

WILLYS TO ACQUIRE GARFORD PLANT

Transaction on Point of Consummation, Willys Purchasing All Common Stock— Garford to Retire from Company.

While reports still are circulating to the effect that having so recently purchased the Gramm Motor Truck Co., of Lima, O., the agreement existing between the Willys-Overland Co. of Toledo, and the Garford Co., of Elyria, whereby the former markets the Garford productions, will be dissolved, John N. Willys is on the point of performing another of his characteristic business strokes which have caused unfeigned and trade-wide surprise. For Willys is about to acquire control of the Garford Co. itself, and unless stumbling blocks interpose, of which there is small likelihood, he will, on Friday next, become possessed of the common stock of the Garford Co., which will place the Garford reins in his hands.

When the transaction is consummated, A. L. Garford, the president of the company bearing his name, will relinquish all interest therein and retire from office. He long has been politically inclined and at this moment appears to be the most likely candidate for the governorship of Ohio in the embryo Progressive party.

The capital stock of the Garford Co. is $2,000,000, of which $1,500,000 is common. In addition to President Garford, the officers are as follows: H. H. Johnson, vice-president; George C. Ford, secretary; Fred N. Smith, treasurer. Directors include E. R. Fanches and Hayden Eames, of Cleveland; Frederick S. Fish, William R. Innis and George M. Studebaker, of South Bend, Ind.

The Garford plant occupies 23 acres and is splendidly well equipped, but many things have combined to prevent the most being made of its facilities. That once in control Willys quickly will remedy this state of affairs is certain. It will give to him not merely direction of the sale of the large, impressive cars—one of them a "six"—and the equally large and imposing trucks

Digitized by Google

which constitute the Garford line, but will place their actual manufacture subject to his will and round out the Willys-Overland line to completeness. The transaction partially explains the recent decision to increase the Willys-Overland capital from $6,000,000 to $15,000,000.

Loses Commissions and Must Pay Costs.

Stock subscriptions and signed stock subscriptions apparently are two entirely different things, as Charles Hallock and Michael P. Caffe, who became involved with the Newark Automobile Manufacturing Co., of Newark, N. J., have learned to their cost. Although Hallock claimed to have sold enough of the Newark company's stock on a 15 per cent. commission basis to entitle him to $5,000 for his work, he has not as much to regret as Caffe, who, as assignee in the case, brought action to recover for the commissions and gave a bond which may necessitate the payment of the costs. The case had its beginning last January in the Supreme Court for New York County, when Caffe was granted an attachment against two of the Newark company's cars on exhibition at the Grand Central Palace show. The attachment was vacated on the giving of a bond, and when the case was tried last week Caffe lost, the defense being that Hallock agreed to get "signed" subscriptions but failed to do so. The disputed stock is said to be in the possession of the Newark company.

Brennan Takes up Truck Production.

After having devoted itself to the manufacture of gasolene engines for some 12 years, the Brennan Mfg. Co., of Syracuse, N. Y., has enlarged its sphere and hereafter will engage in truck manufacture. Three models will be produced—one of two tons capacity, mounting a 35 horsepower Brennan four-cylinder motor, one of three tons capacity and 38 horsepower, and a third, a five-ton vehicle employing a 45 horsepower engine. The vehicles will employ progressive transmission, thermo-siphon water cooling, Bosch dual ignition, cone clutch and semi-elliptical springs, with auxiliary cross springs to carry the overload. The Brennan truck department will be in charge of Robert J. Rothwell, who previously was identified with the truck department of the H. H. Franklin Mfg. Co., of Syracuse, N. Y. On a special order, two trucks were produced in the Brennan plant several months since, and they gave such satisfaction that the decision followed to engage regularly in the manufacture of trucks.

Keeton Acquires Plant in Wyandotte.

The Keeton Motor Car Co., of Detroit, has acquired the plant in Wyandotte, Mich., formerly occupied by the Seitz Automobile & Transmission Co. It will be devoted wholly to the production of six-cylinder cars, the Keeton people having abandoned their original intention to make both "fours" and "sixes."

FORD STOPS OHIO PRICE-CUTTER

Court Grants Injunction Restraining "Co-operative" Company—Patents Involved and Other Unusual Features of Suit.

Until further notice, the Union Motor Sales Co., of Dayton, O., will not sell Ford cars as less than list price, or at any other price, the preliminary injunction prayed for by the Ford Motor Co., of Detroit, having been granted by the United States District Court in Cincinnati on Monday last, 1st inst.

The suit, as the Motor World stated last week, is unusual in that it is the first one in which a prominent automobile manufacturer has brought his patents to bear to prevent price cutting. In presenting their case, which is an action in equity, the Ford people cited no less than 10 patents covering mechanical features of their car, among them Nos. 787,908 for a planetary drive gear for shaft drive, 773,934 for a muffler, 847,405 for a reducing steering mechanism, 879,757 for a piston ring, 1,012,186 for a running gear, and 1,005,186 for a transmission mechanism. The language on the metal plate which is placed on the dash of all Ford cars is also cited; it requires that each purchaser of a Ford car register his name and address and date of purchase with the Ford company, "in order to be protected under warranty of the manufacturer."

In the litigation in the Federal Court in Cincinnati, it was also brought out that the Ford dealers, who are termed "dealers-licensees," are required to report their sales each week to the factory and bind themselves not to sell cars at less than list price, or to supply them to others for that purpose, the contract, which is termed a "license agreement," stipulating for damages in case of a breach of its terms.

The Union Motor Sales Co., which is incorporated under the easy laws of Maine, is one of the so-called co-operative institutions which undertakes to sell cars and accessories at less than list price to its "members" or "subscribers," who are required to purchase one share of stock at a cost of $10. According to the argument presented, the Ford company, in February last, informed an inquirer that the Union Motor Sales Co. "had not been able to deliver a single Ford car," and that "its principal graft was selling $10 worth of stock." The Sales company became possessed of this letter and immediately addressed an indignant communication to the Ford people, demanding a retraction of the statements made, lacking which direful proceedings were threatened. The Ford company promptly replied that it had no intention of retracting anything. Instead, it instituted the present proceedings, in which it asks damages in the sum of $50,000, it being alleged that the defendants had "traded upon the goodwill and high reputation" of the Ford company, and conspired to infringe the Ford patents and to induce dealers-licensees to break their contracts and to otherwise injure the Ford business, and that the same "has been done and is being done, maliciously and fraudulently."

Gramm Organizes a New Company.

B. A. Gramm, who only some two months since disposed of all save a nominal interest in the Gramm Motor Truck Co., of Lima, O., to John N. Willys, of Toledo, has lost no time in carrying out his plans for the organization of another company to produce trucks of his design. It was formally organized last week, under the style Gramm-Bernstein Co. Max Bernstein is president, B. A. Gramm vice-president and general manager and Harry O. Bentley secretary-treasurer. Dudley Bernstein and Fred Biezants, who was Gramm's former superintendent, are the additional directors.

The company has been incorporated under the laws of Ohio with authorized capital of $500,000, of which 3,000 shares are common stock and 2,000 shares preferred. Max Bernstein, the president of the new company, is a millionaire junk dealer and mattress manufacturer, and as Gramm himself does not lack resources, the new enterprise is inaugurated under favorable auspices.

The manufacture of trucks, which will be of 2, 4 and 6 ton capacity, will be carried on in a former paper mill in Lima which has been acquired for the purpose, and in which the necessary machinery already has been installed. It is expected that the first Gramm-Bernstein truck will make its appearance early in October.

Billings Succeeds Barnes in M. A. M. Office.

Claire F. Barnes tendered his resignation as a director and as third vice-president at the regular meeting of the board of directors of the Motor and Accessory Manufacturers, which occurred in the organization's New York offices on Friday last, 28th ult. It was accepted with regret, and F. C. Billings, of the Billings & Spencer Co., Hartford, Conn., was chosen to fill the vacant vice-presidency, and William H. Crosby, of The Crosby Co., Buffalo, N. Y., to fill the vacant directorship. Their terms will expire in January next. At the same meeting, three new members were added to the M. A. M. roll, as follows: Hood Rubber Co., Boston, Mass.; Lefever Arms Co., Syracuse, N. Y., and the American Hardware Corporation (Corbin Screw Corporation Division), New Britain, Conn.

Todd to Produce Sheet Metal Fittings.

The Todd Mfg. Co., of Minneapolis, Minn., of which Frank Todd, former superintendent of the Long Mfg. Co., of Chicago, is the moving spirit, has commenced the manufacture of hoods, fenders, drip pans, tanks and other sheet metal specialties. Todd's associates in the enterprise are P. A. Wolfe and Morgan C. Wood.

MAY THE MERRIEST OF ALL MONTHS

Exports Pass the $3,000,000 Mark and Set up a New Record—France Alone Reduces its Purchases.

Although April, exceeding the automobile exports of January by nearly $200,000, aspired to the position of record month in the history of automobile exportation, its pride of position was even shorter-lived than January's, for the month of May, with a magnificent total valuation of $3,412,790, exceeded April by $686,290, and therefore takes rank as the banner month. Also, compared with the corresponding month of 1911 May shows a gain of $1,555,364 over the exports, a gain of 83 per cent.

Of the total valuation of the May, 1912, exports, $2,963,818 is represented by 3,009 cars, the remaining $448,972 being the worth of parts, which compares with 1,466 cars, valued at $1,513,547 exported in May a year ago, and parts listed at $343,879—a gain in number of cars of over 100 per cent. and in value of nearly 100 per cent. The average price of cars, however, fell from $1,032 in May, 1911, to $951 for the same month of the present year.

Canada, as long has been the case, was the largest taker of America's automobiles, at buying 1,109 cars, valued at $1,352,856, and thereby increasing its April purchases by some $245,000. The next largest importer of cars from the United States was the United Kingdom, which found a market for a product valued at $465,722, running but little ahead of the next geographical division, British Oceania, which received $412,565 worth of automobiles.

But one country recorded a loss, France showing a shrinkage of $22,942. The principal gains in order of magnitude were: British Oceania, $302,752; United Kingdom, $262,183; Canada, $245,751; Asia and Other Oceania, $87,553. The record for the eleven month ending May, 1912, which is $23,179,285, indicates a total for the governmental year ending June 30 of more than $26,000,000. The statistics in detail are as follows:

	May				Eleven Months Ending May					
	1911		1912		1910		1911		1912	
	Quantities.	Values.	Quantities.	Values.	Quantities.	Values.	Quantities.	Values.	Quantities.	Values.

Lion Resumes Operations in Adrian.

Despite reports that the Lion Motor Car Co., whose plant in Adrian, Mich., was destroyed by fire on June 2nd, would locate elsewhere, the company will do nothing of the sort. It has secured another and larger factory building in Adrian and, fortified by the Industrial Association of that city, which has guaranteed $100,000, operations have been resumed and it is stated that the first Lion to be born in the new home will be ready for demonstration within two weeks. and that cars will be ready for delivery within 90 days.

May Tire Exports Show Falling Off.

The valuation of American tires exported from the United States during May, 1912, shows a slight falling off as compared with the value of the tires exported during the same month a year before, the figure for May, 1912, being $272,317 and for the preceding May $310,346, a loss of 12 per cent. While this comparison is unfavorable to 1912, a comparison of exports for the 11-month periods ending with the Mays of 1911 and 1912 shows a gain of 21 per cent.—$1,838,482 as against the latter $2,335,920, a gain of $497,438.

De Lisser Returns to Ajax Tires.

Horace De Lisser, vice-president of the United States Motor Co., has resigned that office to rejoin his earlier love, the Ajax-Grieb Rubber Co., of Trenton, N. J., of which he once was president. He will become chairman of the board of directors. De Lisser will sail to Europe on the Kaiser Wilhelm der Grosse on July 30th and will be absent for six or eight weeks, during which period he will forward plans for the establishment of an Ajax factory in Europe which already are well in hand.

No Michigan Rim Plant for Mott.

Reports which first were printed in Detroit to the effect that the Mott Wheel Works, of Utica, N. Y., had completed arrangements for the establishment of a branch rim factory in Jackson, Mich., are denied in toto by the Mott people. Treasurer Williams states that there is no intention to establish a branch in Jackson, or any other locality.

OWEN-REO CASE STILL UNSETTLED

Jury Disagrees in $500,000 Action and New Trial Probable—Owen Car's "Commercial Practicability" an Issue.

Whether the Owen car is or was "commercially practicable," and whether the Reo Motor Truck Co., of Lansing, Mich., agreed to pay the Owen Motor Car Co., of Detroit, $500,000 damages, are questions which still remain undetermined. The jury in the Wayne County Circuit Court in Detroit, which for four weeks wrestled with the problems and listened to voluminous testimony, was unable to reach an agreement and was discharged last week, which will require that the case be retried, unless it is settled out of court.

The suit grew out of the sale in October, 1910, of the Owen Motor Car Co. to the Reo Motor Truck Co., of which latter R. E. Owen is president. According to the contract, the Reo company bound itself to purchase the Owen machinery, tools, patterns, etc., for the sum of $100,000, payable in Reo truck stock, the stock to be issued to Angus Smith, treasurer of the Owen company, as trustee for the Owen stockholders. In addition, the Reo company agreed to purchase such Owen material as proved acceptable, paying therefor, for a period of one year, the net profits derived from the manufacture and sale of the Owen car, the Reo company retaining but 10 per cent. of such profits. At the expiration of the year, it was provided that the receipts from the sale of the Owen car should be divided on a then mutually agreeable basis, the Owen company agreeing to liquidate its affairs as early as possible, and within five years from the date of the contract to convey a majority of its capital stock to R. E. Olds as trustee for the Reo stockholders.

After the contract had been entered into, the Reo company manufactured 35 Owen cars, of which it sold 31, most of them being marketed through agents of the Reo Motor Car Co., of which the Reo Motor Truck Co. is a subsidiary. The process of

Digitized by Google

manufacture and marketing proved so expensive, however, that the Reo interests decided that the Owen was not a "commercially practicable proposition" and, accordingly, its manufacture was abandoned.

When this came to pass, the Owen interests promptly asserted themselves, making protest and demand that the manufacture of their car be continued. As their protests availed nothing, they represented to the Reo company that its action in the matter had damaged the Owen interests to the sum of $500,000 and, if the Owen story is accepted, the Reo company agreed and promised to pay that amount. When, despite repeated demands, it failed to do so, the Owen Motor Car Co. instituted the action in which the jury last week disagreed.

It was brought out in the testimony that of the parts and materials involved in the contract $22,289.64 worth had been used for free replacements, and that the Owen company had received $27,700 as its share of the receipts from the cars which had been manufactured and marketed by the Reo Motor Truck Co. It also was disclosed that before the suit came to trial negotiations looking toward an amicable settlement had been made, in the course of which the Reo company offered to pay the Owen people a certain sum of money, amount not named, and to turn back to them all of the materials and parts in dispute, or to pay a certain sum and keep the materials and parts, the original price of which, according to the plaintiff's figures, was, approximately, $270,000, and also the jigs, patterns, tools, etc., involved in the transaction, which represented an invoiced valuation exceeding $40,000. Apparently, the money offer was too small and the settlement was refused.

Austins to Become $500,000 Corporation.

James E. and Walter S. Austin, father and son, who, trading as the Austin Automobile Co., of Grand Rapids, Mich., for ten years have built in limited quantities one of the largest and most imposing cars that has come out of the West, finally have admitted new men and new capital to the business, which is to be enlarged and otherwise expanded in every way. George H. Davidson and William R. Shelby, of Grand Rapids, are the men who have become interested and who, with the Austins, are engaged in the organization of a $500,000 corporation, which will take over the Austin interests and seek to make the Austin car a real factor in the trade. Of the capital, $300,000 will be represented by common stock and $200,000 by 6 per cent. preferred. The shares will be offered for public subscription and it is probable that a bonus of 50 per cent. common will be given with each purchase of preferred.

The Packers Motor Truck Co., of Wheeling, W. Va., has opened a New York office in the United States Rubber Building, 1784 Broadway. A service station also will be maintained on West 42d street.

DECIDES PREST-O-LITE PATENT DEAD

Judge Kohlsaat, in Searchlight Case, Disagrees With Eight Other Federal Courts—Old Law Involved.

Although seven United States District Courts and one United States Circuit Court of Appeals have decided that the Claude and Hess patent under which the Prest-O-Lite Co., of Indianapolis, manufactures and markets its product is alive and is still entitled to a lease of existence for some five years, Justice Kohlsaat, of the United States District Court for the Northern District of Illinois, has decided that the patent is quite dead. His decision, rendered last week in the long pending action brought by the Prest-O-Lite people against the Searchlight Gas Co., of Chicago, sustained his denial of a preliminary injunction, and until the case is fought out in the Court of Appeals, gives the Searchlight company the right to continue its business as heretofore, within that judicial district. The numerous other decisions favorable to the Prest-O-Lite company are its basis for carrying the case higher.

The whole line of suits hinges about a point of patent law. The statute prior to 1897 held that a foreign patent taken out in the United States expired at the same time as the foreign patent, but the law was amended in 1897, and the limitation was removed, but the limitation still was imposed upon patents for which application had been made prior to the change in the law. The application for the Claude and Hess patent was made prior to 1897, but it was not granted until December 25, 1900, when it was given the number 664,383, while the English patent is number 29,750 and officially expired June 30, 1910. The English and American patents are to the lay mind somewhat similar, and the contention of the defense in the Prest-O-Lite cases is that the American patent is the same as the English grant, and since application was made prior to 1897 it has expired. The Prest-O-Lite contention, which has thus far been upheld, is that the English patent covers a "process," consisting of a method of holding the gas in solution and of regulating other details, while the American patent covers an "apparatus," consisting of the tank, valves, gas and whole outfit. The patent has been upheld by United States courts in Michigan, Indiana, Missouri, California, Washington, Colorado and Texas and the Circuit Court of Appeals of the 6th circuit. Judge Kohlsaat's is the first decision in the negative.

White Wins in Dealership Dispute.

Difficulties encountered by The White Co., of Cleveland, O., with the White Motor Co., its former Brooklyn dealer, after considerable litigation in the New York City Court, were adjudicated last week, when the former was given a verdict for $4,422.70 against the dealer and Philip S. Saitta, a New York attorney, the amount in dispute arising from notes which had been given. These notes were alleged to have been given when the dealer signed the White contract and to have been endorsed by Saitta. When the contract was broken after various disagreements, the White Co. sought to collect on the paper.

Creditors Seek to Prevent Van-L Transfer.

Although the Van-L Commercial Car Co., of Grand Rapids, Mich., was supposed to have been taken over in March last by the Commercial Service Truck Co., a $175,000 corporation of which Philip Moran is president, it appears that the transaction did not proceed to such a point as to prevent the filing of a petition in bankruptcy against the Van-L concern; for such a petition was filed last week in the United States District Court in Grand Rapids, which was followed by another petition of the same creditors, Arthur Gelock and John W. and W. L. Landman, praying for the appointment of a receiver. They allege that the Van-L company has transferred, or attempted to transfer, its assets to the Commercial Service Truck Co. without authority and without consideration, and in fraud of the Van-L creditors and stockholders, and that the Commercial Service Truck Co. was organized for the sole purpose of taking over the Van-L assets.

Weed Denied Preliminary Injunction.

Because the Weed tire chain adjuster patent, No. 953,673, had not been adjudicated—that is, had not been previously the basis of a suit against an alleged infringer—the application of the Weed Chain Tire Grip Co. for a preliminary injunction against Charles Weiland and the 35% Automobile Supply Co., of New York City, was denied this week in United States District Court for the Southern District of New York, and the Weed people will be unable to get a decision of any kind until the suit has been threshed out in court. The patent covers a device consisting of springs extending from the chain grips toward the center of the wheel, holding the grips against the tire.

Republic to Increase Capital to $10,000,000.

Directors of the Republic Rubber Co., of Youngstown, O., have recommended an increase of capital from $4,000,000 to $10,000,000, the recommendation being now before the stockholders for approval, which there is small doubt will be given. The new stock will consist of $6,000,000 common and $4,000,000 preferred. It was less than two years ago that the Republic capital was increased from $2,500,000 to $4,000,000. The expansion of the business in that period has been such as to necessitate another and larger increase. The establishment of a reclaiming plant is one of the things in view, which will be brought about when the new money is rendered available.

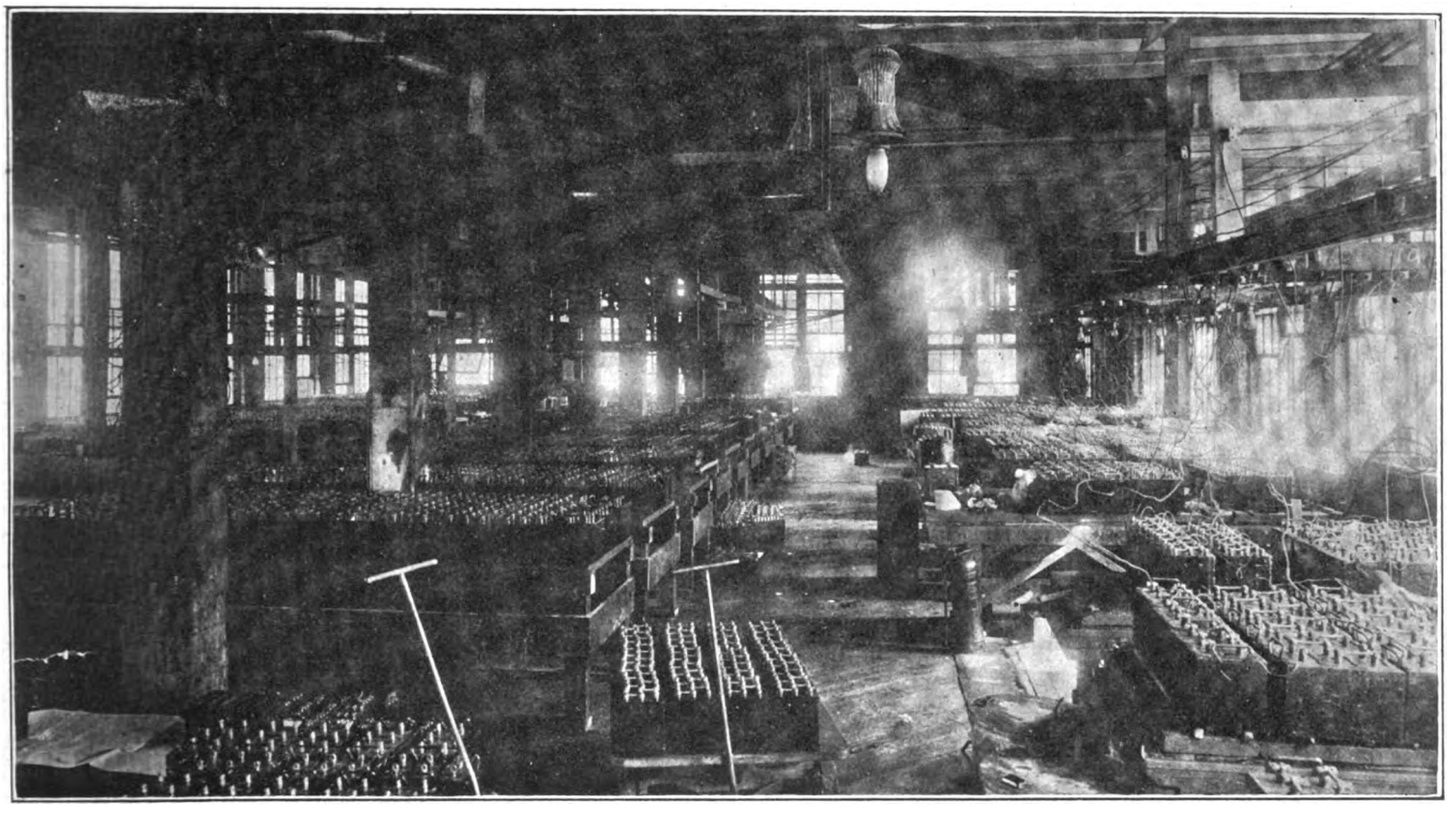
THE WEEK'S INCORPORATIONS

Detroit, Mich.—Capital Auto Lock Co., under Michigan laws, with $10,000 capital; to manufacture accessories.

Saginaw, Mich.—American Steam Truck Co., under Michigan laws, with $10,000 capital; to manufacture motor trucks.

Portland, Me.—Essenkay Sales Co., under Maine laws, with $50,000 capital; to deal in motor accessories. Corporators — D. J. Snow, H. P. Sweetster, and others.



—Charles Leviton, Jesse Lowenhaupt, Sigmund E. Loeb.

Muncie, Ind.—Feeney-Hurd Co., under Indiana laws, with $20,000 capital; to manufacture automobile accessories. Corporators—Edmund J. Feeney, James H. Leffle, Carl E. Hurd.

Chilton, Wis.—Hippe Motor Car Co., under Wisconsin laws, with $15,000 capital; to deal in motor cars. Corporators—Robert

Lima, Ohio. — Gramm - Bernstein Co., under Ohio laws, with $500,000 capital; to manufacture motor vehicles. Corporators —B. A. Gramm, Max Bernstein, Fred Biezants, Dudley Bernstein and H. O. Bentley.

Westfield, Mass.—Westfield Motor Truck Co., under Massachusetts laws, with $100,000 capital; to manufacture and deal in motor vehicles. Corporators — Ernest L.

INTERIOR OF A STORAGE BATTERY DEVELOPING ROOM—VIEW IN WILLARD FACTORY IN CLEVELAND

South Bend, Ind.—Otis Motor Car Co., under Indiana laws, with $10,000 capital; to manufacture motor cars. Corporators—N. L. Otis, J. B. Beattie, Gilbert Squires.

Florida, N. Y.—Florida Garage Co., under New York laws, with $6,000 capital; to operate a garage. Corporators — Calvin C. Crawford, Mary E. Crawford, Alfred E. Winser.

San Francisco, Cal.—Peninsular Automobile Co., under California laws, with $15,000 capital; to deal in motor cars. Corporators—H. E. Holmes, John D. Gish, W. T. Chubbuck.

Chicago, Ill.—Washington Motor Livery Co., under Illinois laws, with $75,000 capital; to operate a motor livery. Corporators H. Hippe, Herman Gierow, F. J. Egerer, George J. Berger.

Toledo, Ohio.—Rubernix Mfg. Co., under Ohio laws, with $10,000 capital; to manufacture tire filler. Corporators—Edward O. McLain, L. E. Fike, M. N. Dickey, L. M. Florey, F. E. Calkins.

Jersey City, N. J.—Republic Auto Tire Vulcanizing Co., under New Jersey laws, with $25,000 capital; to deal in tires and accessories. Corporators — W. Merkel, P. W. Stainard, M. Levine.

Lancaster, Pa. — Keystone Automobile Exchange, under Pennsylvania laws, with $100,000 capital; to deal in motor cars. Corporators—James W. White, Clarence J. Jacobs, Harry W. Davis.

Hull, Henry W. Hallebourg, Walter F. Mogill.

Nashville, Tenn.—Seaton Wheel Co., under Tennessee laws, with $130,000 capital; to manufacture automobile wheels. Corporators—Granberry Jackson, Samuel S. Lord, B. C. Seaton, John T. Landis, J. Ray Boone.

Columbus, Ohio.—Everitt Auto Sales Co., under Ohio laws, with $30,000 capital; to deal in motor cars. Corporators—Horace K. Dobson, Amos F. White, Elmer F. McConaha, H. H. Kellenberger, A. W. Daving.

Columbus, Ohio.—Federal Auto Accessories Co., under Ohio laws, with $2,000 capital; to deal in motor accessories. Cor-

Digitized by Google

porators—J. R. Loofburrow, N. M. McDonald, W. C. Weatherhole, E. J. Mace, M. L. Mace.

Cleveland, Ohio.—Auto Owners Co., under Ohio laws, with $25,000 capital; to deal in motor cars and accessories. Corporators—P. A. Leighly, W. K. Stanley, H. N. Pettibone, Frank H. Forest, John Grienheimer.

Schenectady, N. Y.—Brenner-Hardt Co., under New York laws, with $3,000 capital; to deal in motor vehicles. Corporators—Adam E. Brenner, 517 Hamilton street; Louis Hardt, Amelia Hardt, both of 151 Green street.

New York, N. Y.—D. K. & D. Co., under New York laws, with $5,000 capital; to manufacture motors. Corporators — Eckford C. DeKay, Sidney G. DeKay, both of 50 West 9th street; Andrew C. Dam, 141 West 39th street.

Brooklyn, N. Y.—Saratoga Auto Co., under New York laws, with $5,000 capital; to deal in motor cars. Corporators—George D. Smith, 2123 Metropolitan avenue; Harry A. Bogard, Emily J. Bogard, both of 18 Furman avenue.

Buffalo, N. Y.—Automobile-Vehicle Corporation, under New York laws, with $20,000 capital; to deal in motor vehicles. Corporators—L. A. Kenyon, 274 Dewitt street; Frank H. O'Neil, 823 Genesee, street; Otto A. Hagelin, 533 Oak street.

New York, N. Y.—Goldfinger Auto Renting Co., under New York laws, with $2,000 capital; to rent automobiles. Corporators—Benedict Goldfinger, Richmond Hill; Walter E. Fisher, 73 West 92d street; Isaac Wolf, 205 West 136th street.

New York, N. Y.—C. & T. Auto Specialty Co., under New York laws, with $10,000 capital; to deal in motor accessories. Corporators—George F. Connelley, 3505 Broadway; John J. Treacy, 3 West 63d street; John R. Hunt, 867 39th street.

New York, N. Y.—American Society of Automobile Owners, Inc., under New York laws, with $10,000 capital. Corporators—Robert S. Kennedy, 790 Riverside avenue; Joseph C. Murray, 29 Broadway; Alexander Woods, 228 Hart street, Brooklyn.

New York, N. Y.—Resilient Punctureless Tire Co., under New York laws, with $200,000 capital; to manufacture tires. Corporators—Seth H. Sheldon, 106 West 71st street; Flossie H. McCready, Leroy McCready, both of 62 West 93d street.

New York, N. Y.—Republic Motor Co. of New York, Inc., under New York laws, with $500 capital; to manufacture motor trucks, etc. Corporators—Frank H. Twyeffort, 67 Hancock street, Brooklyn; Stephen C. Fiero, 159 Bainbridge street, Brooklyn, Ernest J. Ellenwood, 34 Maple Court, Flatbush.

Poughkeepsie, N. Y.—A. B. Manufacturing Co., under New York laws, with $200,000 capital; to manufacture automobile devices. Corporators—Max M. Ketzen, 237 West 111th street, New York City; Jacob Litchenstein, 995 Union avenue, New York City; Ralph H. Raphael, 520 West 122nd street, New York City.

New York, N. Y.—Service Recorder Co., of New York, under New York laws, with $10,000 capital; to manufacture automobile devices. Corporators—Harold F. Seymour, 1923 East 90th street, Cleveland, Ohio; Frederick Seymour, 55 Prospect street, East Orange, N. J.; Benjamin N. Levy, 82 West Washington Place, New York City.

Independence Acquires Carter Assets.

At the public sale of the Hyattsville (Md.) plant of the bankrupt Carter Motor Car Corporation last week, the property was bid in by P. M. Galvin, acting for the Independence Motors Co., which was formed for the purpose by H. O. Carter and other principals of the defunct company. Originally, Carter formed the Washington Motor Car Corporation to acquire the property and continue the manufacture of the Washington car, but for some reason it was replaced by the Independence company. The production of the Washington car will be continued, but henceforth it will be styled the Independence car. The price paid at the auction last week was $12,000, the sale including the real estate, buildings and factory equipment. It is understood that the common stock of the Independence company will be issued to the former stockholders in the Carter Motor Car Corporation, in order that they may feel that they have saved something from the wreck.

Banker's Son Causes Mercer to Sue.

An escapade on the part of the son of a New York bank president is responsible for an action brought last week in the Supreme Court for New York County by the Mercer Automobile Co., of Trenton, N. J., against the Auto Credit Co. and the Auto Owners' Sales Co., of New York City, to establish the ownership of a Mercer car which the Trenton company supposed it had sold to the bank president's son. The young man corresponded with the Mercer company and subsequently the car was delivered to him, whereupon he drew a check on his father's bank. When the check was returned marked "No Funds," the Mercer people instituted inquiry and found the car in the possession of the defendants, who claimed they had advanced money on it. The Mercer company promptly replevined the car, and now sue to establish true ownership.

Hitch in Parish-Orson Settlement.

Although the attorney for the Parish Mfg. Co., of Reading, Pa., manufacturer of frames, among other things, withdrew his complaint when that company's case against the Orson Automobile Co. was reached in the New York City Court some two weeks ago, the expected settlement of the dispute did not immediately materialize. While it was understood by the Parish people that their bill of $501.11 for labor performed and materials would be paid, the check was slow in appearing, and accordingly application was made for the reinstatement of the cause on the calendar, and the judge ruled that such would be done unless payment were made by June 26. This date passed without settlement, and if the check does not appear by the time court opens in the Fall the serving of an order on the calendar clerk will place the case where it was before overtures of settlement were made. The trouble grows out of a contract for 100 frames made by the Parish company with the Orson concern when the latter, with much gusto, threatened to make some splurge in the automobile manufacturing field. The contract never was completed, and the Parish company sued for lost profits and money expended on what work it had done. In offering to compromise and settle, the Orson company stipulated that whatever it paid be deducted from the total amount of the contract were completed.

Alfred N. Mayo Succumbs to Operation.

As the result of an operation for cancer performed the same afternoon, Alfred N. Mayo, treasurer of both the Fisk Rubber Co. and the Knox Automobile Co., died late Friday evening, June 28th, at the Wesson Memorial Hospital, Springfield, Mass. He had returned from Chicago four weeks before, suffering from what was believed to be ptomaine poisoning, but which was found to be the cancer which proved fatal. Mr. Mayo was born in Springfield in 1844 and had resided in that city all his life. He long had been prominent both socially and commercially in the city, his interests in the Fisk and Knox companies being but two of several industries with which he was identified. He was a veteran of the Civil War. He is survived by his mother, his wife and three daughters, one of whom, Mrs. Harry G. Fisk, is the wife of the president of the Fisk Rubber Co.

Gemmer's President in Fatal Accident.

Edward A. Skae, president of the Gemmer Mfg. Co. and an officer of the Federal Motor Truck Co., among other Detroit enterprises, and also the head of the Michigan State Automobile Association, was instantly killed on Thursday last, June 27th, when an automobile in which he was a passenger skidded off the road and overturned in a ditch near Birmingham, Mich. Skae, who was born in Canada in 1871, had been a resident of Detroit for some 20 years, and was prominent both in commercial and social circles. He leaves a mother, a widow and four children.

Rassel Becomes the Toledo Truck.

Following the withdrawal of W. De Arnold, the Rassel Motor Car Co., of Toledo, has changed its name to the Toledo Motor Truck Co. De Arnold for some time had been seeking to acquire the Rassel property, but, failing, withdrew to form a company bearing his own name, which, however, has not yet come into being.

A. L. Hurr is about to erect a garage in Shakopee, Minn.

Joseph B. Vincent of Ceres, Cal., is about to open a repair shop.

M. G. Bally, of Springfield, Ore., has purchased an interest in the Gittins Garage.

C. H. Hildreth, 2d, has opened a garage, 65 x 100 feet, on Seaver street, Worcester, Mass.

J. C. Brown has purchased the Union Garage in Lakeland, Fla; H. D. Sloan was the former owner.

The Wheeling Mold & Foundry Co. is about to enter the garage business in Wheeling, W. Va.

Orville McDonald of Mapleton, Minn., has leased the Benz Building and will remodel it into a garage.

John Sievers of Valpariaso, Ind., has secured authority to build a garage 80 x 100 feet; it will cost $6,000.

Under the style, Buckingham Auto Garage, J. W. Buckingham and J. T. Peck have "opened up" in Welsh, Ia.

The firm of White, Ware & Leatherbee, of Boston, Mass., has been dissolved. It handled the Bergdoll car.

Charles Wason, of 2909 Euclid avenue, Cleveland, O., has secured permission to build a garage; it will cost $3,000.

W. K. McKnight, of Alexis, Ill., has become a dealer; he has arranged to represent the Henderson Motor Car Co.

Hammonton Garage and Machine Works is the style of a new concern in Hammonton, N. J. W. S. Turner is the proprietor.

Frank Robinson of Healdsburg, Cal., has purchased the interest of his partner, Sidney Groshong, in the Fitch Mount Tavern Garage.

Permission has been granted Nelson L. Elmer, of Springfield, Mass., to erect a garage at 13-21 Cross street; the cost will be $32,000.

The Florell Auto Co., of Iron Mountain, Mich., is about to open a garage in Negaunee, the same State; a livery service also will be operated.

Thomas Girling of the Girling-Warner Automobile Co., Anoka, Minn., has purchased the Warner interest; Girling will continue the business.

Under the style First Garage & Motor Co., H. W. Smith has opened for business at 222 Huron street, Toledo, O. He has accommodations for 40 cars.

Under the style, the Service Garage, a new company has been organized in Plainfield, N. J., with E. A. Craig as manager; Henderson cars will be stocked.

Frank P. Davis has taken over the J. S. Richtey garage business in Merced, Cal.; Davis formerly was in the automobile trade in Bakersfield, in the same state.

Claude Oswalt of Leavenworth, Kan., has purchased an interest in the Clyde Wilson Garage in Gravity, in the same state; the new style will be Wilson & Oswalt.

James A. Binney, of 587 Boylston street, Boston, Mass., has become a Henderson dealer; he will maintain a three-story service building apart from his sales rooms.

J. M. McDonald has opened a garage in Wethersfield, Conn. He was for six years in the employ of a Hartford automobile firm, and therefore does not lack experience.

Vaughan & Less, proprietors of the Century Garage, in Watsonville, Cal., have sold their interests to Robert Neill and Claude Redwine; the latter will manage the business.

A. B. and Mason Towle, formerly of Joliet, Ill., are about to enter the automobile field in Cincinnati, O., as Cadillac dealers; they will incorporate under the style Cadillac Motor Sales Agency.

Benjamin Ciegel, of Detroit, Mich., is securing estimates on a service building and garage to be erected at Lafayette, 12th and West Fort streets; the structure will represent an expenditure of $60,000.

J. R. Overstreet, of Fort Worth, Tex., has entered the trade in that city, handling the Lambert line; his territory comprises Texas, Oklahoma, Arkansas, Louisiana, Colorado, New Mexico and Arizona.

George Ostendorf, who was associated with H. E. Crosby as Franklin dealers in Buffalo, N. Y., under the style George Ostendorf Co., has purchased Crosby's interest; Ostendorf will continue the business alone.

The Mercer Automobile Co., of Trenton, N. J., has opened a Kansas City (Mo.) branch at 1524 Grand avenue; Roy O. Kendall, formerly connected with the D. A. Kendall Motor Car Co., of that city, is manager.

The Mattoon (Ill.) Refrigerating Co. has entered the automobile trade and will handle Henderson cars; George O. Cobb will manage the business, which will be conducted in a new two-story sales and service building.

The Seeberger Motor Co., located on North Elm street, Creston, Ia., has gone out of business, the stock of accessories being purchased by H. W. Edaburn, owner of the Cadillac Garage; Seeberger will remove to Portland, Ore.

Bruno Seibel, who has won considerable fame on the Pacific Coast as a racing driver, will open a garage in the Bidwell Building on West Third street, San Bernardino, Cal., when the building is completed; he is now connected with another garage.

W. A. Wicks, for the past five years a member of the engineering staff of the H. H. Franklin Manufacturing Co., of Syracuse, N. Y., has resigned to engage in the retail trade in Seattle, Wash. Quite naturally, he will handle the Franklin line.

Leo Collier, former manager of the Lawrence Auto Co., of New Castle, O., has sold out his interests and will become identified with the business of his father-in-law, Milton B. Coombs; the latter is proprietor of the Buick Garage in Youngstown, O.

The Essenkay Sales Co. of California and Arizona has been formed in Los Angeles to act as Pacific Coast distributer of the tire filler of that name. L. N. Brunswig, of the Brunswig Drug Co., of Los Angeles, is the moving spirit in the new organization.

S. L. Buchanan and T. D. Levering, owners of the Motor Truck Co., 407 Rosabel street, St. Paul, Minn., have purchased the lease of the Genge Power Vehicle Co. to the premises at 353 Main street; they plan to establish a large commercial vehicle business.

Edward Dixon and M. Gray, former employes of the Square Deal Auto Co., of Monroe, Wis., have purchased the interest of Emil Hokanson of Madison. With A. L. Maddrell, who has been manager of the business, they continue under the old style.

W. F. Kneip, for six years commercial car engineer for the H. H. Franklin Mfg. Co., of Syracuse, N. Y., and E. F. Williams, a member of the testing department, have resigned to enter the retail trade in Kansas City, Mo. They will, of course, handle the Franklin.

Glenn A. Tisdale, Franklin dealer in New York City, has purchased a controlling interest in John J. Kerwin & Co., automobile repairers, at 248 West 80th street. The latter firm has handled the Franklin repair work, which, with the sales business, is now under the one head.

The Auto Tire & Repair Co., which conducts a general tire and repair business in Toledo, O., has changed its name to Peerless Rubber & Tire Co. and removed its place of business from Ontario street to the new Thatcher building in Madison street. Elmer Allmeroth retains the managership.

The stock of the West Side Garage and Motor Co., of 160-162 West 101st street, New York City, has been sold by M. M. Hayward & Co., acting for the estate of

Digitized by Google

Abram Christie, to Thompson J. Wheeler, president of the New Taxicab & Auto Co. The buyer has a ten-year lease of the premises.

Herbert J. Ellis, former head of the Ellis Brick Co., of Toledo, O., has purchased an interest in the McLeary Engineering Co., of that city, and became its treasurer on Monday last; the company, which, besides repairing and rebuilding cars, handles the Buick line, will increase its capital and scope of business.

The Federal Motor Car Co., operating a garage on Henry street, Oakland, Pa., has been placed in the hands of a receiver, William J. Zahniser, following the filing of a bill in equity in Common Pleas Court by Charles E. Pette. The latter, a stockholder and creditor, states there are mortgages of $47,000 against the company's property.

"Studebaker Service Station" is the name on the signboard over the place of business of the Brandenburg & Pearson Co., which has opened up at 446 D street, San Bernardino, Cal. E. C. Brandenburg, of the firm, formerly was with the Weinstock-Nichols Co., and Pearson was Studebaker agent in San Diego. Of course, Studebaker cars are handled.

The Canada Overland Co., Ltd., of Regina, Saskatchewan, has changed its name to the United Motor Co., Ltd. F. R. Mahoney is manager of the concern, which has the Overland agency. George R. Rastall was the head of the original company and he gave the Willys-Overland Co. a lot of trouble by pre-empting and registering the name "Overland" in his own name. He, however, has no connection with the United Motor Co.

Recent Losses by Fire.

Chicago, Ill.—The Prest-O-Lite Co., 1912 South 52d street, plant damaged. Loss, $15,000.

Fresno, Cal.—William Helm, J street, garage and five cars destroyed. Loss, $10,000.

Jacksonville, Fla.—Switzer & Hickling Garage, 220 West Monroe street, garage and two cars damaged. Loss, $7,000.

New York, N. Y.—Eureka Garage, St. Nicholas avenue and 122d street, damaged by exploding air tank.

Dealer Sues and Gets Deposit Back.

That the dealer who fails to take the cars he agreed to take and who believes he has some right to the return of all or a part of his deposit may not be entirely in the wrong, if he has facts to substantiate his case, is indicated by a decision rendered last week in Municipal Court of New York City, where the Rhode Island Motor Car Co. of Providence, R. I., was given a verdict of $498.36, including costs, against the Correja Motor Car Co., of New York City. The Rhode Island concern signed up as dealer September 1, 1910, and deposited $450, which, it is claimed, was to be returned to it at the end of a year, the dealer also contracting for a certain number of cars. Two runabouts were shipped and one was delivered to a customer, the other being retained as a demonstrator, and immediately the Rhode Island concern began sending complaints to the Correja company, their burden being that gasolene tanks leaked, front springs broke, transmission gears were defective, differentials gave trouble, brakes were loose, brake drums were badly worn, a rear axle was weak and worn and the Providence man's story was filled with woe. The Rhode Islanders claimed they tried to get the Correja company to make good, but, being unsuccessful, they brought suit for the return of their deposit.

Changes Among Prominent Tradesmen.

C. D. Clement has resigned the management of the Spokane branch of the Goodyear Tire & Rubber Co. He will return to old San Francisco, whence he came, and re-engage in the automobile business.

Fred Nichols has been appointed assistant sales manager for the Chalmers Motor Co., of Detroit. Previously he was connected with the Chalmers agency in Boston.

George H. Phelps, manager of the Studebaker Corporation's retail branch in Boston, has been promoted to the post of manager of the New York branch. He succeeds Charles F. Redden, who half-resigned.

For the second time, Ralph Estep, long the advertising manager for the Packard Motor Car Co., of Detroit, has resigned that office. Estep's first resignation was tendered about a year ago, but he then reconsidered it and returned to duty, but this time he is out "for good."

Gilbert J. Loomis, for five years sales manager for the Speedway Motor Car Co., of Dayton, O., has resigned that office, his resignation becoming effective August 1st. It is his purpose to devote himself to the development of an automobile specialty in which he has been interested for some time.

C. F. Young has been appointed assistant general manager of the Regal Motor Car Co., of Detroit. Young enjoyed experience with the Electric Vehicle, Pope and American Locomotive companies, but latterly he has been a member of the engineering and designing staff of the Lozier Motor Co., in Detroit.

After having served the Maxwell-Briscoe Motor Co. and its successor, the United States Motor Co., for eight years, B. E. Stimson has resigned the management of the United Motor Minneapolis Co. His brother, E. B. Stimson, assistant manager, resigned with him. The management of the establishment has been taken over by O. W. Klose.

J. A. Graham has been appointed manager of the Studebaker branch in Minneapolis. He succeeds to the vacancy caused by the resignation of C. R. Newby. Orrin S. Wilson, manager of the Studebaker's Denver branch, has been appointed manager of the big corporation's Des Moines establishment, succeeding C. F. Stewart, who resigned, the vacancy in Denver being filled by the promotion of J. C. Beck, assistant manager. All of the men have been identified with the Studebaker interests for several years.

Martin Forms Indiana Tractor Company.

Growing out of the recent visit of C. H. Martin to Indianapolis, there has been organized in that city the Martin Tractor Co., which has been incorporated under the laws of Indiana with an authorized capital of $350,000. In addition to Martin, the directors of the new company are Hugh R. Richards, F. B. Davenport, Edward D. Moon and George D. Thornton. Their purpose is to manufacture in quantities the Martin three-wheel tractor, which at present is produced under a shop license by the Knox Automobile Co., of Springfield, Mass. The Indianapolis company has not yet secured a factory, but it is stated that several buildings are under consideration.

Corbin Takes Over Brown Speedometer.

Having for some time manufactured the Brown speedometer for the New York company of that name, the Corbin Screw Corporation, of New Britain, Conn., has taken over that instrument and hereafter will market it directly through its sales staff and branches in New York, Philadelphia, Chicago and San Francisco. Henceforth it will be styled the Corbin-Brown speedometer, and Col. W. C. Brown, the inventor, will serve as sales manager of the Corbin corporation's new speedometer department. The Corbin-Brown speedometer is of a centrifugal type.

R. C. H. Establishes Branch in 'Frisco.

To better handle its increasing business on the Pacific Coast, the R. C. H. Corporation is this week establishing a branch and service station in San Francisco. It is located in a three-story structure on Ellis avenue, near Van Ness, which is in the heart of the new automobile district in that city. It will be used as a distributing point for the entire West, it being the intention to have on hand at all times a sufficient supply of R. C. H. cars and to take care of rush orders.

Timken Denies Purchase of Detroit Site.

Someone in Toledo, O., must be possessed of a fertile imagination, for although it was printed in bold, black type that the Timken-Detroit Axle Co. had acquired a site of several acres in that city, the exact location of which was given, the Timken people state that they have done nothing of the sort. They not only have acquired no property in Toledo, but have no intention of establishing a plant there. They are, however, very considerably enlarging their Detroit factory.

Entered as second-class matter at the New York Post Office, November, 1900.

NEW YORK, JULY 4, 1912

PERMANENT HIGHWAYS AND ONE THAT EXISTS.

It is to be hoped that the campaign inaugurated in Bridgeport, Conn., for the construction of a brick or wood block or other permanent roadway from New Haven to the New York State line will meet with the measure of encouragement and support which it so richly deserves, and that the seed sown will spread to the furthermost parts.

Probably no main road is more extensively traveled than that which lies between New York and New Haven, and probably none is so usually in a more indifferent condition. At various times and in various parts the macadam has been laid and relaid and patched and repatched, but always the road returns to its indifferent state, making plain what has long been apparent, and what the Bridgeport campaigners are emphasizing, i. e., that macadam as a road surface has had its day. Why those entrusted with the construction and upkeep of highways refuse to recognize and admit the fact is beyond comprehension. For certainly latter-day experience abundantly has proven macadam to be a mere stop-gap and money-waster. The fact never was better illustrated than in New York City itself, where for years the authorities have resurfaced parkways and other highways time and again only to have them go to ruin; yet the resurfacing continues, and today one of the most frequently and most recently resurfaced thoroughfares, Riverside Drive, in certain parts closely resembles a plowed field.

On the other hand, and on the New York-New Haven-Boston highway, there has existed for many years on the outskirts of Portchester, N. Y., a stretch of permanent highway which cannot but serve as an object lesson for all who are not beyond acquiring knowledge. It well may be doubted whether brick will prove a satisfactory road surface, but whether brick or wood blocks, it is undoubted that the unit form of construction which they entail cannot but prove so expensive as to at least give pause to those who consider their use. But the Portchester pavement, whatever it may be, apparently a "poured" pavement, resembling asphalt, if its uniformly smooth condition and its apparent resistance to wear and tear for over-long periods, may be accepted as a criterion, offers an answer, if not the answer, to all who seek a really permanent highway. While other roads in all directions have gone to decay, only to be renewed and to decay again, the Portchester pavement has remained hard, smooth, clean, dustless and rutless—an object lesson for all.

HOT WEATHER'S EFFECTS ON TRUCK PERFORMANCES.

The rising temperature of summer brings with it a peculiar condition which, while in some degree affecting gasolene trucks, is much more keenly felt by users of heavy electric vehicles. As a direct result of the softening of the asphalt of the city streets the truck tires sink deep in the yielding stuff and the progress of a heavily loaded vehicle is the equivalent of a continuous hill-climb.

While the most conspicuous result is a very considerable increase in the consumption of electricity or of gasolene, as the case may be, there necessarily must follow the general wear and tear of a long hill-climb. The current consumption phase of the matter is the most troublesome, however, for in the case of an electric vehicle having to cover a distance that necessitates the use of the entire normal output of the battery in cool weather, the additional draw in hot weather is a cause for worry because it may, and often does, cause exhaustion of the battery before the end of the trip.

Obviously the best thing to do would be to go to the root of the trouble and build roads less sensitive to heat. As this seems impossible, or at least impracticable at present, the only alternative to letting matters go as they are is to increase the bearing surface of the tire on the ground. Tires on heavy trucks usually are made about as wide as is practicable, so there remains the expedient of increasing the wheel diameter, which is open to two objections: it necessitates a greater ratio of reduction in the gearing and it means added expense for wheels and tires. In the earlier days of motor car construction the comparative crudity of gear work made it necessary to keep the road wheel diameter as small as possible in order to minimize gearing difficulties. With the highly efficient gearing that now is available, however, to say nothing of worm drive systems, the reduction problem is by no means so serious, and the added expense of the larger tires would be largely, if not entirely, offset by the added mileage due to the added wearing surface. There would be a saving in power and in wear that would amount to a considerable figure during the life of the car. Large wheels are easy riding, and while the question of luxury does not enter into commercial vehicle problems, the question of crystalization does, and lack of vibration means delayed crystalization. Makers of gasolene cars have done far more work with large diameter wheels than have electric truck builders, with satisfactory results; and there seems to be no important reason, save that of first cost, why makers of heavy battery trucks should not turn their attention in this direction.

HAYNES HOST AT "HOUSE PARTY"

Managers, Dealers and Others Attend Three-Day Function at Kokomo Factory—Instruction Mixed With Fun.

The latest product of the Haynes Automobile Co., of Kokomo, Ind., was not a motor car—though, of course, motor cars figured conspicuously in it—but a three-days "House Party" that was intended to make Haynes agents and managers and parts and material men and press men, who were the guests of the occasion, better acquainted with the Haynes "house," the Haynes hosts, the Haynes product and with each other.

Each of the three days—June 25, 26 and 27—had its particular features of interest, but perhaps the most original, not to say startling, event was the opening performance, so to speak, of the second day, which was designated as "Mechanical Day." This was the "construction of a complete motor car while you wait," with all the details and adjustments explained by Chief Engineer Frank Nutt and Superintendent Zehring. Other days were by no means lacking in interest, however. From the opening of the first session at "headquarters," when C. B. Warren, general manager of the Haynes company, explained "The House Party and Its Objects," to the final winding-up banquet at the Y. M. C. A. on the evening of the third day, there was something going on all the time; the sessions were held at "Headquarters," at the factory and at the Y. M. C. A. assembly hall, and each of the guests and each of the hosts was called upon for a ten-minute talk, each man being assigned a subject that he was especially happy in dealing with. When General Manager Warren had started the ball rolling by explaining what it was all about, Elwood Haynes, whose remembrance of things pertaining to the early history of motor cars is of an encyclopaedic nature, largely because he himself helped to make that history, talked about his "Recollections," and during the course of the feast of wit and flow of soul—not to mention various occasions when more substantial things were in evidence—there were talks on a wide range of motor car subjects, running all the way from advertising to ignition, and from steel to selling. There was certainly no lack of appropriateness in the assignment given to Steelman, of the Terre Haute Malleable & Mfg. Co., who talked about steel castings. Dr. Stanley F. Krebs was called upon on three occasions, discoursing on "His Honor, the Other Fellow; how to read and handle different types and kinds of human nature," "The Sale Hill, and how to get the customer to the top of it," and "Two Snakes in Eden; the conquest of fear and worry in business."

A banquet at which the honors were done by Elwood Haynes, Conrad Wolfe, the Haynes company's attorney, as toastmaster; J. W. Johnson, A. E. Starbuck, Dr. Stanley Krebs, and A. L. Thalman as official story-teller brought the "House Party" to a happy conclusion. Between sixty and seventy ten-minute talks were listed in the artistic little programs that were printed for the occasion, and though not all of those invited were able to attend the affair, there were plenty to make the occasion one not soon to be forgotten.

May Responsible for Slight Import Gain.

Official statistics show that during the month of May the importation of automobiles into the United States increased one in number and $7,713 in valuation as compared with the same month of the preceding year—76 as against 75, their sources of values being as follows:

	May, 1911.		May, 1912.	
	No.	Value.	No.	Value.
Imported from—				
United Kingdom	19	$36,941	11	$28,324
France	26	62,442	41	95,965
Germany	13	26,460	5	10,114
Italy	7	12,799	11	17,424
Other countries	10	19,404	8	13,932
Total cars	75	$158,046	76	$165,759
Parts of		47,846		21,493
Total cars and parts.		$205,892		$187,252

The imports of parts fell from $47,846 in May, 1911, to $21,493 in that month of this year, a loss of 55 per cent. Statistics for the eleven month period ending with May show that 921 cars, valued at $2,033,254, were imported, as compared with 771 cars, valued at $1,642,329 for the eleven months ending May, 1911, a gain of slightly less than 20 per cent. in number and 18 per cent. in valuation. The parts imported during the eleven months ending May, 1912, were valued at $283,736, and at $336,168 for the eleven month period terminating with May, 1911, a loss of 15 per cent.

No Let-up in Exportation of Engines.

Although the absence of earlier statistics makes impossible a comparison of 1912 automobile engine exports with those of preceding years, the numbers of engines exported during May, 1912—571—is within five of the monthly average for the 11 months ending May, 1912, during which period 6,344 were shipped out of this country. The May shipments totaled $67,627, an average of $118 per motor, while the 11 months' valuation, $726,280, gives an average of $114.

Clark Settles Troubles and Resumes.

Although the Citizens' Industrial Association of Shelbyville, Ind., filed suit against the Clark Motor Car Co., of that city, for liquidating damages and foreclosure of mortgage, the much-troubled company apparently has found a way out of its many difficulties, which led to the filing of an involuntary petition in bankruptcy in February last. At any rate, after several suits had been settled the plant was reopened last week and is again in operation without change of officers or stockholders.

July 4, Davenport, Ia.—Davenport Automobile Club's annual hill climb on Rock Island hill.

July 4, Macomb, Ill.—Track races on the fair grounds track.

July 4, Los Angeles, Cal.—Mt. Washington Automobile Association hill climb on Mt. Washington hill.

July 4, Wildwood, N. J.—Straightaway races, under the auspices of the North Wildwood Auto Club.

July 4-5, Butte, Mont.—Track races under the auspices of the Butte Motor Club.

July 4-5, Tayor, Tex.—Track races under the auspices of the Taylor Automobile Club.

July 4-6, Old Orchard, Me.—Beach races under the auspices of the Old Orchard Automobile Association.

July 5-6, Tacoma, Wash.—Road races under the auspices of the Montamara Festo Automobile Commission.

July 7, Fort Wayne, Ind.—Track races promoted by E. A. Moross.

July 13, Forestville, N. Y.—Hill climb under the auspices of the Forestville Motor Club.

July 15-16, Cleveland, Ohio—Reliability run under the auspices of the Cleveland News.

July 15-20, Milwaukee, Wis.—Reliability tour, under the auspices of the Wisconsin State Automobile Association.

July 21, St. Louis, Mo.—Track races under the auspices of the Universal Exposition Co.

July 22, Dallas, Texas—Farm and Ranch Tour under the auspices of the Dallas Automobile Club.

August 8-10, Galveston, Tex.—Beach races under the auspices of the Galveston Automobile Club.

August 23-24, Elgin, Ill.—Chicago Motor Club's national stock chassis road races.

September 2-3, Indianapolis, Ind.—Races on the Motor Speedway, promoted by the Indianapolis Motor Speedway Co.

September 7, Hadine, Minn.—Track races promoted by the Minnesota State Fair Association.

September 17, Milwaukee, Wis.—Grand Prize road race under the auspices of the Milwaukee Automobile Dealers' Association.

September 21, Milwaukee, Wis.—Vanderbilt Cup race on the Greenfield course, under the auspices of the Milwaukee Automobile Dealers' Association.

EASTERN SPEEDWAY TAKING SHAPE

Metropolitan Association Finally Elects Officers and Employs Engineers—Outline of Plans for Huge Enterprise.

After apparently lying dormant for several months, the Metropolitan Motor Speedway Association suddenly has awakened almost full-grown. It has been incorporated with an authorized capital of $1,500,000, officers have been elected and offices established, one in New York City and the other in Newark, N. J., and all other plans seem to be well in hand. Indeed, the projectors are so sanguine that their plans to accomplish the gigantic task of converting the expanse of swampland lying between Jersey City and Newark, N. J., into a modern speedway and motordrome will be completed, that they have selected July 4, 1913, as the date for the opening event—an international 500-mile race.

The officers of the association are: President, H. E. Hoyt, who is vice-president of the American Potash Co.; vice-president and general manager, A. R. Pardington, former manager of the Long Island Motor Parkway; treasurer, Theodore F. Keer, who is vice-president of the Newark Trust Co., and secretary, W. H. Osborne, who is secretary of the Commercial Maintenance & Motor Co. Fred J. Wagner, the A. A. A. starter and race promoter, is one of the directors, and with Pardington will direct and oversee most of the actual work of preparation; and as these men have had large experience the work may be said to be uncommonly well in hand.

A New York city office has been opened in the United States Rubber Building, 1784 Broadway, where Pardington will make his headquarters. The engineering staff, however, will be quartered in Newark in the Ordway Building, 207 Market street.

It is expected that ground will be broken, or, more correctly, land will be dumped into the marshland during the present month and that the speedway will be completed within one year.

While the promotion of automobile races is the underlying basis of the project, it is the intention to so design the speedway that the plant will be available for all manner of outdoor contests and exhibitions. The track proper will be a brick oval, two miles in circumference, 60 feet wide, except on the turns, which will be 75 feet in width, and scientifically banked, of course. The infield will be laid out to permit the holding of aviation meets, baseball, football and field and track athletics generally, also circuses, Wild West shows and the like.

According to present plans, automobile races will be run fortnightly, provision having been made for an elaborate lighting system. Grandstands, with boxes and promenade seats, with a seating capacity of 200,000, will be erected the entire length of the straightaway stretches, and parking accommodations for 10,000 cars will be arranged in the infield, which will be accessible by three double-track tunnels. Garages, repair and machine shops, pits, a hotel and club house, and a restaurant are among the things which are included in the huge plans; and as the total population within a radius of 20 miles is 7,000,000 the projectors have a rich and a big field from which to draw.

The Speedway location is within 12 minutes of downtown New York by means of the Hudson tubes. The Erie, Pennsylvania, and D., L. & W. railroads each will have stations on the property, permitting patrons to pass directly from the trains to the grandstands. The Public Service Corporation of New Jersey lands passengers on two sides of the property, with a five-cent fare from Newark and Jersey City. From New York the fare is 10 cents. Boulevards from Jersey City, Hoboken, Weehawken and interior New Jersey lead to the property. Ferries from 130th street, 42d street. 23d street, Christopher, Desbrosses, Cortlandt and Barclay streets have an automobile capacity of 3,000 cars per hour. The Speedway is convenient to all points in New Jersey by rail, trolley and highway, and by automobile and train from Philadelphia, Trenton, the Oranges, and all points within 200 miles.

Weight Decides Cincinnati's Fuel Contest.

Perhaps if a severe thunder storm had not overtaken the 26 contenders in the Cincinnati Automobile Club's efficiency or fuel consumption contest, which occurred on Saturday last, June 29th, their scores might have been better; certainly the going would have been pleasanter. As it was, however, Horace Heisey, driving a Buick, covered the 41 miles from Cincinnati to Hamilton, O., and return with a consumption of but 1.32 gallons of fuel, which is "considerable economy," but not quite so good as the record of E. J. Carpenter in a Franklin, who consumed but 1.30 gallons. As Carpenter's car weighed 2,960 pounds, however, as against 2,835 pounds for Heisey's Buick, the formula which applied gave first honors to the latter. Third place went to J. A. Duchemin, who drove a Selden and who completed the course with an expenditure of 2.07 gallons of fuel, his car weighing 4,420 pounds. The formula which decided the standing of the contestants required that weight of the car be divided by the quantity of gasolene used, thus fixing the ratio of the quantity of fuel consumed to the net weight of the vehicle.

Watertown Forms Automobile Club.

At a meeting which resulted in the formation of the Watertown (Wis.) Motor Club, the following were elected to office: President, A. R. Barker; vice-president, Dr. A. W. Meyer; secretary, Max Kusel; treasurer, Max Rohr.

BURMAN REGAINS "MEAL TICKET"

Menenghetti Holds Remy Prize Only One Week—Burman Has Two Big Days on Laurel Track.

Louis Menenghetti, who only the week previously had defeated Robert Burman in five out of six heats which were run for the Remy Brassard and trophy, passed the "meal ticket" back to the gentleman of Blitzen Benz fame when three heats for the trophy were contested on Friday and Saturday last, June 27th and 28th, on the one-mile track at Laurel, Md. That the act was not voluntary, however, was generally guessed by the spectators who were within earshot when the Cuban—for Menenghetti proves to be a Cuban and not an Italian—discovered that the crankshaft of his Mercedes had parted, which put him out of the running in the first heat, which the promoter, R. E. Shadel, had programmed for the first day of the racemeet.

Burman also took first place in two Class E events which were included in the first day's program; the shorter of the two, which went for five miles, he completed in 5:22, driving the Cutting; the second, which went for 25 miles, he completed in 27:32, likewise in the Cutting, his victory giving him the Matoline trophy. His performances for the first day of the meet ended when he drove an exhibition mile in the Benz in :58¾, establishing the local track record. The three remaining events which were embraced by the program of Friday included two Class C events for cars of 161-230 and 231-300 inches displacement, respectively, both of which went for five miles, and a five-mile free-for-all handicap, and were respectively won by I. C. Barber, who drove a Warren and finished in 6:15; John Raimey, who completed the course in an Ohio car in 5:37, and E. A. McDonald, who won in 6:19½.

The chief interest on Saturday centered in the Australian pursuit, in which Burman passed in succession John Raimey in an Ohio, I. C. Barber in a Warren and Campbell in a National, the pursuit lasting for more than eight and a half miles. Burman's time in the Benz was 8:19¼. Burman also came to the front in a five-mile Class E event, in which five contenders started and which was completed in 5:34. Raimey in the Ohio was second, following Burman's Cutting car across the tape 19 seconds later. The five-mile free-for-all handicap attracted its full share of attention and was won by McDonald, who started from scratch and finished in 6:05½. Barber in the Warren, who started 55 seconds ahead of the winner, took second position.

Barber won the Class E, 161-230 inches event, which went for five miles with three contenders, and completed the distance in 6:07¾ in a Warren. A five-mile Class E event and a five-mile special event went to

Digitized by Google

Raimey in the Ohio and Blair in the Mercer, respectively. Raimey's time was 5:55, while Blair needed 6:04½ to cover the same distance. An exhibition mile which Burman drove in 54¼, lowering the record made on the first day of the meet by 4½ seconds, completed the program. The summary:

Friday, June 28th.

Three miles, for the Remy Brassard and trophy, first heat—Won by Robert Burman (Benz); second, E. A. McDonald (Benz); third, I. C. Barber (Warren). Time, 3:20.

Twenty-five miles, Class E, for cars with piston displacements not over 600 inches—Won by Robert Burman (Cutting); second, John Raimey (Ohio); third, Howard W. French (Lozier). Time, 27:32.

Five miles, Class C, cars with displacements of 161-230 inches—Won by I. C. Barber (Warren); second, Frank G. Stewart (Reo). Time, 6:15.

Five miles, Class C, cars with displacements of 231-300 inches—Won by John Raimey (Ohio); second, C. C. Fairman (Kline). Time, 5:37.

Five miles, Class C, cars with displacements of 451-600 inches—Won by Robert Burman (Cutting); second, J. W. Minker (Kline); third, H. W. French (Lozier). Time, 5:22.

Five miles, free-for-all handicap—Won by E. A. McDonald (Benz); second, C. C. Fairman (Kline); third, H. W. French (Lozier). Time, 5:14½.

Saturday, June 29th.

Five miles, for cars of 161-230 inches displacement—Won by I. C. Barber (Warren); second, Stewart (Reo); third, Blair (Warren). Time, 6:07⅜.

Five miles, Class E, for cars under 450 inches displacement—Won by John Raimey (Ohio); second, I. C. Barber (Warren); third, Blair (Mercer). Time, 5:55.

Five miles, special—Won by Blair (Mercer); second, I. C. Barber (Warren); third, Stewart (Reo). Time, 6:04½.

Three miles, second heat for Remy Brassard and trophy—Won by E. A. McDonald (Benz); second, Robert Burman (Benz). Time, 3:11¼. Final heat—Won by Robert Burman (Benz); second, E. A. McDonald (Benz); third, Menenghetti (Mercedes).

Five miles, Class E, for cars under 600 inches displacement—Won by Robert Burman (Benz); second, John Raimey (Ohio); third, I. C. Barber (Warren); fourth, Blair, (Mercer). Time, 5:34.

One mile, time trial—Robert Burman (Benz). Time, 54¼.

Five miles, free-for-all handicap—Won by E. A. McDonald (Benz), from scratch; second, I. C. Barber (Warren), 55 seconds handicap; third, John Raimey (Ohio), 20 seconds handicap); fourth, Campbell (National), 25 seconds handicap. Time, 6:05½.

Eight and one-half miles, Australian pursuit race—Won by Robert Burman (Benz); second, John Raimey (Ohio); third, I. C. Barber (Warren); fourth, Campbell (National). Time, 8:19¼.

A. A. A. REPRESENTATIVE RESIGNS

Others Suspended for Defiance of Orders in Santa Monica Road Race—New Rule is Promulgated.

Because of the remarkable situation which developed in connection with the Santa Monica road race on May 4th last, in which, despite repeated and emphatic instructions, two so-called Flanders cars were permitted to compete, although equipped with special motors, and the following day were permitted to figure in track events at Los Angeles as "E-M-F" cars, the A. A. A. contest board very graciously has "unanimously decided to accept the resignation" of E. G. Kuster as the official representative of the A. A. A. contest board in Southern California.

Not quite so graciously, the board has declared ineligible for official appointment in any capacity until January 1st next R. P. Hillman, of Los Angeles, who refereed the road race, and has disqualified A. M. Young, of Los Angeles, the promoter of both the road race and the track meet, for a similar period. This awful punishment will enable the flagrantly disobedient and defiant referee and promoter to be ready for duty before the next Santa Monica race comes to pass.

"In view of the extenuating circumstances, due apparently to a conflict in authority in the interpretation of the contest rules," according to the official statement, "it was decided to approve the awards as made by the referees in these two contests, but that in future events sanctioned by the contest board the nomenclature of special cars must be clearly defined."

The times made in the Santa Monica race will not be recognized, as the A. A. A. has failed to obtain possession of the original timing record.

Growing out of the Santa Monica trouble, the A. A. A. contest board has adopted and promulgated the following rule, which is designed to prevent similar proceedings:

"No car with a bore, stroke and piston displacement of a different size from the regularly catalogued product of a manufacturer shall be entered in any sanctioned event until its manufacturer shall have blanks provided for the purpose by the contest board, sworn certificates giving the bore, stroke, number of cylinders, total piston displacement, horsepower, and year and model name of the cars, and such cars must be officially entered, programmed and advertised in strict accordance with such registration. All other cars must be entered, programmed and advertised in strict accordance with catalogued specifications."

The A. A. A. also has made more specific regulations concerning repair pits for road races by promulgating Rule 113, which requires that "there shall be located at the start and finish line one repair pit for each car started, not less than 15 feet long and 8 feet wide. The pits must be located on the right of the course in the direction in which cars are traveling. If located on the same side and in front of the grandstand, there must be an intervening distance of not less than 15 feet between the pits and the stand."

Gilbert Wins Speed Judgment Contest.

Of the 36 members of the Springfield (Mass.) Automobile Club who on Thursday last, June 27th, participated in its sixth annual speed judgment contest over a 21½ mile course to Forest Lake, T. B. Gilbert proved that he was able to obey the "know thy pace" admonition. He most closely followed the rules laid down to drive at a 12-mile rate for the first 25 minutes of the run, at a 20-mile rate for the next 42 minutes and then to continue the journey at 12 miles an hour, and by so doing he won the Fisk trophy. Gilbert in his Maxwell arrived at Forest Lake just 16 seconds later than he should have done had the rules been followed to the letter; Walter S. Barr, who drove a Chalmers, and Henry Clave, in a Stearns, won second and third honors, respectively. The prizes which were awarded, of which there were 20, embraced everything in the accessory line from a Klaxonette to an inner tube, but each prize was useful and pertinent. Various athletic games were indulged in by the club members through the afternoon, and for the winner of each of these contests there was a prize.

New York's "Motor Carnival" is Off.

The motor carnival, which was to have been a feature of the New York Hotel Men's League's summer-long festival, is off—at least, until September next. It was due to occur during the present month, but late last week the astonishing discovery was made that at this time the "automobile business is at a low ebb and so many motorists and people connected with the trade are on vacations, and so few dealers have 1913 models ready for delivery," that prospect of a successful carnival is so indistinct as to be painfully visible. The proposed carnival aroused little, if any, enthusiasm, but, nevertheless, September 9th to 14th have been set as the dates for a new trial.

Tour Becomes "Boost Denver" Affair.

Ten motor car loads of Denverites, out to "boost" their home town, are now on a tour from that city to Chicago and return, the event being what remains of the Denver Chamber of Commerce's proposed contest from Denver to New York City and back, which was launched with considerable eclat but which was curtailed because of lack of entrants. The contest feature also was eliminated. The "boosters" left Denver June 25 and the schedule calls for seven days en route to the Windy City, three days tarrying in that town and nine days on the way back to the Colorado capital, making nineteen days' absence from home.

THE LOG OF THE AUTOMOBILE ENGINEERS' CRUISE

The Work That Was Done During the Three-Day "Terra-Marine" Mid-Summer Meeting of the S. A. E. and the Hilarious Play That Relieved the Monotony of More or Less "Dry" Professional Sessions—Detroit Convention and a Similar Outing Likely Next Year.

ONE OF THE MANY SIMILAR WELCOMING BANNERS THAT FLUTTERED IN DETROIT LAST WEEK

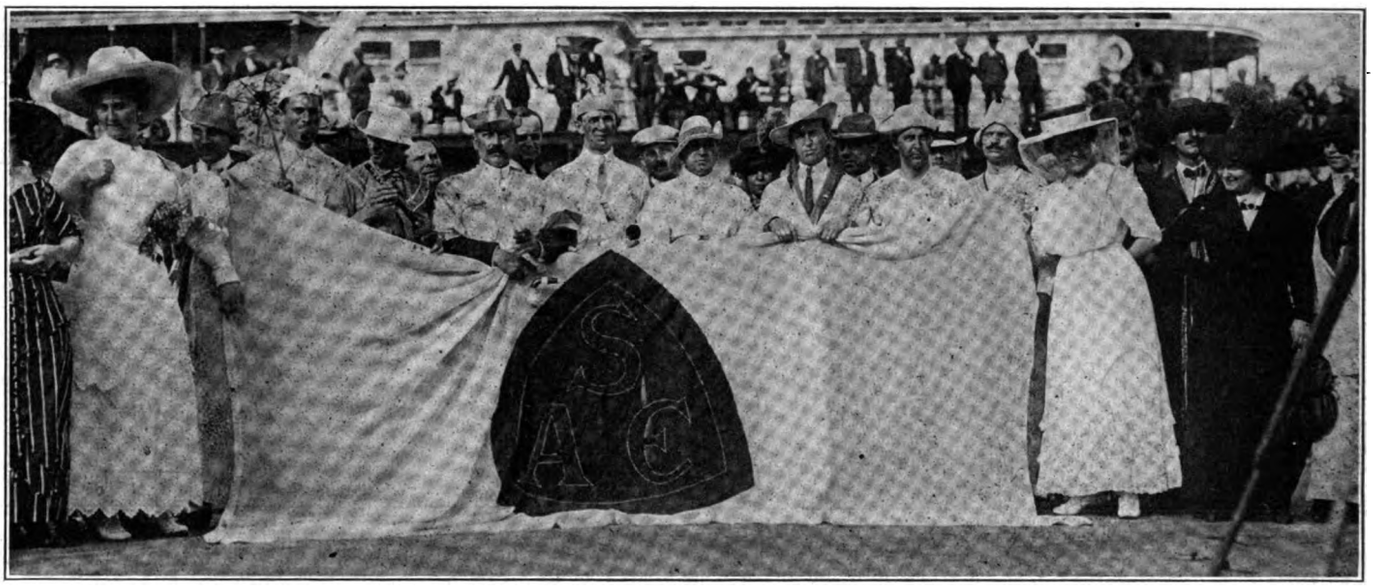
Just as exploration naturally follows discovery, so has exploration of the work which has been done in the past year by the Society of Automobile Engineers followed the "discovery" of the society by its members at the summer meeting held in Dayton, O., in June, 1911. Some 400 members of the society gathered in Detroit, Mich., on Thursday last and during the two days which followed and which were spent on the reaches of Lake Huron, the delving into past performances and the exploration of records that was made was thorough enough to reveal that the S. A. E. has become more than ever a factor that must not only be reckoned with in the solution of the multiplicity of problems that arise to harass or encourage the manufacturer, but one that has become well-nigh indispensable.

One of the principal things which the convention served to emphasize is the avidity with which engineers turn to the society with their problems and the solutions of problems that at one time or another have proven knotty. At the annual meeting which was held in New York City last January, in conjunction with the national shows, this feature was not so apparent, probably because manufacturers and designers and engineers were more concerned with problems involving the disposal of their outputs for the coming season than they were with engineering troubles. During Thursday and Friday and Saturday last week, however, conditions were entirely different. For the nonce, selling policy and selling plan were relegated to the background—insofar as that was possible, for it undoubtedly is true that manufacturing, with the feature of cost ever paramount, bears directly on selling policy—and those who foregathered concerned themselves more directly with matters pertaining to engineering.

Not even the fact that the professional sessions were held "far from the madding crowd" out on the heaving bosom of Lake Huron, served to detract attention from the business in hand. In this connection, however the use of the word heaving is a misnomer. There was not even a single heave, to cause, as President Donaldson said, "sympathetic heavings." The air was singularly clear and still and the only ruffles that marred the lake in the immediate vicinity of the good ship City of Detroit II, on which the engineers were, figuratively speaking, held prisoners, were those caused by the ship's own paddle wheels. During the two days the weather was as nearly ideal as it is possible ever to obtain. It is said that the efforts of the Detroit committee on entertainment were responsible for the climatic conditions, nor is the allegation denied by the committee itself. Be that as it may, neither old J. P., nor Neptune, or whoever the deity who presides over the usually troubled waters of the Great Lakes, conspired to interfere with either business, of which there was much, or pleasure, of which there probably was more. However, business came always before pleasure, and though there were those who inclined to let the latter interfere with the former, as was evidenced by sundry poker games in the smoking room on the ship and sundry other "social" gatherings on the broad decks while the professional sessions were in progress, the meetings were well attended on the whole, though little that was either illuminating or highly instructive was brought out during the discussion of the various papers that were read.

Officially, the summer convention was opened in the Convention Hall of the Hotel

Digitized by Google



Pontchartrain on Wednesday morning, 26th ult., with a meeting of the Standards Committee, at which some 50 committeemen were present, and at which the work of the various divisions during the past year was reviewed and reports were gotten in shape for presentation at the formal society meetings. It was not until the following morning, however, that the convention really opened, and by 10 o'clock in the morning the Convention Hall was well filled. President Donaldson opened the session with his presidential address, in which he reviewed briefly the activities of the society in the past year. As always has been the case, the work of standardization which is being actively pushed and which at present has reached to a significance that is appreciated by few who are not intimately connected with the movement, formed the basis for a goodly portion of his address. In conclusion he raised a laugh and hearty applause by referring to the standardization work in the terms of the old and well-known proverb anent eating a pudding to discover its particular delights. "An old proverb says," he informed his hearers, "that the results of the pudding are in the chewing of the pudding string; and so while the mastication of the string has occupied the exclusive attention of some, others already have digested the standardization plums and appear to be well fed and happy."

Standardization, in fact, was one of the themes which was well defined in the general harmony which prevailed at the meetings. It was always cropping up in unexpected places during discussion. Nearly every one referred to it at one time or another, and on more than one occasion the work was made the butt for witticisms. Such "funnings," however, were merely in the nature of safety valves to relieve the excess of good humor that prevailed and leave minds cleared for a better conception of the question.

The antagonism against standardization which exists in the minds of some men still persists, though its pointedness has been partially blunted during the past year, probably because of the good work that has been done and the benefits which even now are accruing. The contrary view was well reflected in the remarks of Lord Montagu, who as a leading British authority with a peculiar familiarity with conditions "on the other side," addressed the meeting in Detroit at the request of President Donaldson. There was a tendency, he said, for standardization, unless carefully carried out along well defined lines, to damp out the enthusiasm of invention. Standardization should not be pressed too far if healthy competition was to be fostered. This was particularly the case at present in view of the growing international character which the automobile industry is assuming. Such standards as were adopted should be scrutinized with a view to determining their applicability to foreign as well as American practice, emphasis being laid on the necessity for providing uniform tire and wheel sizes. Standardization in England was progressing, though with none of the speed that has marked the movement in America. In conclusion, he remarked what is obvious, i. e., that standardization cannot possibly be attained for a number of years, which statement he backed up by citing the condition of the locomotive industry, which, though in the course of standardization for 30 years or more, still was far from its ultimate development.

In replying to Lord Montagu, Henry Souther, past president of the society and at present chairman of the Standards Committee, reiterated the statement that standardization means not necessarily revolution but a gradual readjustment. Standard, he said, means approved construction, and is not the result of one man's experience but of many. As regards the damping of inventive enthusiasm, he remarked that if it could be proven that square wheels were better for commercial vehicles, square wheels would be used in spite of all the standardization work which the S. A. E. might accomplish, for, he concluded, "Mr. Montagu, you cannot down the Yankee inventor."

Immediately following the addresses by Messrs. Souther and Montagu, the routine business of the meeting was taken up. Not the least important fact that was brought out was that since the last summer meeting the membership of the society has increased some 60 per cent., the total enrollment at present being 1,300. The increase represents the election of 206 members, associates, juniors and affiliates since January, 1912. The treasurer's report which followed revealed that the balance on hand as a result of the past six months' activities amounts to upward of $3,000.

S. A. E. KIMONO CORPS DISPLAYS THE OFFICIAL BANNER TO WONDERING NATIVES

It goes without saying that during the time the engineers were in Detroit, the city was thrown wide open for their benefit. Practically all of the many automobile factories in the city, and there are 40 of them by actual count, invited inspection of their plants, though owing to the short amount of time between the adjournment of the meeting on Thursday and the sailing of the society's floating headquarters, the Ford plant was the only one which could be visited. As a matter of fact, the visit had been arranged beforehand and special trolley cars were provided to convey the delegation to the factory. Arrived, there was not a locked door in the whole plant, and members were permitted to wander at will through the maze of automatic machinery and gaze in wonder while some 325 automobiles were turned out under their very eyes. During the time the inspection of the Ford plant was in progress, the ladies of the party, 80 or 100 strong, were entertained by the Detroit Board of Commerce. An

Digitized by Google

automobile trip occupied part of the morning and afternoon, and later a theater party was the order.

The first night on the ship was a wild one for many. The ladies of the party retired early, but the men, staid presidents of companies, consulting engineers, and other high dignitaries and officials, made merry far into the night. They paraded around the decks and saloons in lock step singing, "Hail, hail, the gang's all here;" they instituted "rough house" proceedings that would have done justice to a gathering of college freshmen; and altogether they had a glorious and uproarous time. Fun and unful place, half rolling country and half flat. Strangely enough automobiles are absolutely foreign to its shores; their use is prohibited. As a consequence, it is probable that there are more horses and carriages to the square inch. so to speak, than in any other locality.

It was after dinner on board that the exhuberance of spirits became apparent. Headed by Albert Champion, F. E. Moskovics, and a few other choice spirits, a party of perhaps thirty diversion seekers marched into town singing at the tops of their lungs and proceeded to load up with tin whistles, toy drums, zoboes and other Champion's example, donned wrappers, brightly colored kimonas, and even plain white petticoats. All were topped off with sun bonnets, immense straw hats, Indian head gear and grass hats, and if the natives of the erstwhile quiet little town of Mackinac viewed the parades and speeches and songs which followed, as the ravings of a crowd of escaped lunatics, it is small wonder. Later, the appearance of one of the number in a blanket, with a bow and arrows, caused another general change in fashions, and it was not long before the whole crowd, which increased in size as the time for sailing approached, took on the

"POCAHONTAS" AND THE "INDIANS" GROUPED ABOUT PRESIDENT DONALDSON, SECRETARY CLARKSON, EX-PRESIDENTS COFFIN AND SOUTHER AND OTHER S. A. E. OFFICIALS IN THE BOW OF THE SHIP

limited joy were the order of proceedings and as it was a "private party," none other than S. A. E. members and their wives being permitted on the ship, which was charered for the occasion, there was no one to put a damper on the ardor of the pleasure seekers.

But the "high jinks" that were instituted the first night were merely forerunners of what was to take place the following day at Mackinac Island and during Friday night. It is safe to say that the inhabitants of Mackinac Island never have seen a greater "hurrah" than that which was given when after a night and a day on shipboard the noisy faction of the delegation went ashore to stretch its legs and to find fresh diversion.

The Island of Mackinac itself is a beautinoise producing instruments. With these they serenaded the principal hotels and created an infernal din. The novelty of such accoutrements having worn off, some one in the party disappeared into a dry goods store and reappeared arrayed in a long white night shirt (over his clothes, of course). Needless to say he made an almost instant hit with the others, who immediately proceeded to "go and do likewise." But there were not enough sleeping garments to go the rounds, and Albert Champion, who really was the leading spirit in all the doings, compromised on a resplendently colored lady's wrapper, a string of immense beads and a poke bonnet. Soon all the rest discarded other more or less intimate garments which covered their ordinary clothing and following appearance of a band of Indians on the war path. Not even the war paint was missing, and at last reports some of the "Indians" were endeavoring to remove a too liberal application of indelible pencil. On board ship, activities were continued, sporadic parades around the saloons being the order, and it was along in the "wee sma' hours" before seriously minded persons could get to sleep.

The following day, just before a stop was made at Port Huron, the "Indians" donned their war paint and fineries for the benefit of the photographer, and were pictured in groups and singly on deck. Needless to say, they went ashore togged out as they were, though probably owing to the daylight, activities were of a less spectacular and vociferous character. Probably a dozen

Digitized by Google

"braves," arms, legs and all painted in fierce characters and S. A. E. emblems, shed blankets and feathers and dove overboard to the accompaniment of squeals of delight from the ladies and an admiring circle of small boys. The paint did not wash off.

Everybody, with the possible exception of the members of the ship's crew, whose duty it was to clear away the debris, had a glorious time, and as it was the purpose of the committee in charge of entertainment to see that just that happened, everybody was satisfied. For those who were disinclined to take part in the war dances and other highly diverting antics of what speedily became known as "that noisy bunch," there was deck shuffle board, cards and boxing. As was to be expected, Champion and Moskovics took an active part in the procedings within the "squared circle." They were put on in the principal bout of the tournament, the heavyweight class, and gave an exhibition of sparring which, if not scientific, at least was amusing. Neither has a superabundance of hirsute covering on his cranium and each selected the top of the other's head as the fairest target at which to aim wonderfully executed "uppercuts" and "corkscrews." It is not a matter of record how much weight each lost as a result of the strenuous "milling." Nor is it known who is entitled to the championship, though, as befits his name, Champion quite naturally claims it.

Over all the proceedings, the S. A. E. official banner waved. During the time the ship was under weigh it flew from the bow on the staff which on Sundays and state occasions carries the Union Jack, and when the delegation trooped ashore the banner was taken along as a matter of course and used as an effective foreground for several of the group photographs that were taken. The banner itself was of white silk with the S. A. E. emblem in yellow occupying a blue triangle in the center. The same emblem was emblazoned on a hurriedly constructed kite that three or four of the engineers attempted without success to fly from the hurricane deck.

But, as already has been stated, the two days' cruise was not all pleasure. A goodly amount of real work was done, though owing to the length of the several papers that were read and the rambling discussion that followed them, a considerable portion of the program had perforce to be abandoned. Thus, for instance, the papers by John Wilkinson (The Effect of Relation of Bore and Stroke in Automobile Engines), J. M. Thomas (Stability of Automobile Propeller Shafts), S. I. Fekete (Method of Brake Capacity Determination), and L. J. Lane (Leaf Springs), [all of which were printed in the Motor World last week], held over until the semi-annual meeting in January. Also, the topics which had been suggested for "discussion provided time permitted" had to be omitted.

In view of the importance of Detroit as an automobile manufacturing center, it is altogether probable that the next summer meeting, or part of it at least, will be held there also. It is planned to extend the cruise to include Sault Ste. Marie, in which case the trip will occupy three days instead of two. However, nothing definite has been decided, though invitations from both San Francisco and Indianapolis, the latter being facetiously styled by one member as "the suburbs of Detroit," have been received and will be considered. It is unlikely, however, that either will be accepted, for Detroit has a strong claim on the affections of the engineers and has made overtures for the next convention, which, in view of the success of the one just completed, likely will bear considerable influence.

It was at the first formal gathering on board ship that appreciation of the splendid work that during the past two years had been done by Secretary and General Manager Clarkson found official recognition

MR. AND MRS. SOUTHER AND COFFIN AND COKER CLARKSON AT FORT MACKINAC

in the form of a presentation. For some time past the Indiana section of the S. A. E. has been actively engaged in collecting a fund with which to purchase an automobile which it was planned formally to present to Clarkson during the convention. Unfortunately, though the fund now has reached to proportions that will permit the purchase of a really first-class car, the committee in charge is undecided what brand will be most suitable. In lieu of the actual machine being presented, therefore, Clarkson was notified of the intention of the society to honor him and presented with a miniature limousine, electrically lighted and equipped with a "spring starter," which it was pointed out was built thoroughly in accordance with S. A. E. standards. Clarkson was not the only member of the society to receive a remembrance of the occasion, however. Just before the boat docked at Detroit on the return trip, every member was presented with a small, leather covered, loose-leaf notebook, on the cover of which was embossed the S. A. E. emblem and owner's name in gold.

In the reports that were rendered by the various divisions of the Standards Committee was revealed a small part of the tremendous volume of work that has been done during the past year, most of it under the active guidance of Coker Clarkson. Clarkson's supervision of the work was necessary mainly for the reason that much of that which has been accomplished has been the direct result of mail inquiries, in which the position of manufacturers and designers was ascertained, before the matters formally were laid before committee meetings.

Despite the amount of work that has been done, however, and indicating the spirit of cautiousness with which investigations are being prosecuted and standards recommended, the reports of but three divisions of the Standards Committee were accepted by the S. A. E. as recommended practice. The other reports all were in the nature of progress reports, and as explained by Henry Souther, who is chairman of the committee as a whole, their recommendations still are brewing.

Probably the most important of the three reports which were accepted and ordered printed for insertion in the S. A. E. data book as recommended practice, was the report of the Carburetter Fittings Division, of which G. G. Behn is chairman. In presenting the report, it was explained by Chairman Behn that the division has been working toward standardization of carburetter flange and gasket and pipe connection sizes for a very long time, and that three times previously had the report come up for acceptance, only to be returned for alterations. In its present form, however, such alterations as had been suggested and which in the opinion of those whose work it had been to draw up the report had been made, and after an exceptionally brief discussion in which Souther championed the acceptance of the report as submitted and gave it his earnest support, it was unanimously voted accepted.

One other report which was accepted, or rather virtually accepted inasmuch as it was voted that the Standards Committee be empowered to act upon it for the society, was the report of the division which had under advisement the standardization of magneto mountings and dimensions. For a long term of years it has been the universal practice among magneto manufacturers to provide instruments for four and six-cylinder engines in which the taper on the armature shaft was different. The principal point which was settled in the report concerned this taper, which was recommended to be made the same for both four and six-cylinder instruments. The taper adopted, however, now is standard for four-cylinder instruments; hence there will be but little change necessary. Several other matters of a minor nature also were covered in the report, which, as has been said, was turned over to the Standards Committee as a whole for action. Inasmuch as Chairman Souther has come out strongly in favor of the acceptance of the report and

Digitized by Google

his views were in accordance with those of a number of other members present, it is altogether likely that the report will become in actuality recommended practice.

The third report which was accepted as recommended practice was that of the division which had undertaken the standardization of electric lighting systems. Recommended practice in this case, as accepted, consists in using the Eddi-Swan base sockets in place of any other base sockets for lights, which, in the case of head lamps, are not to exceed 20 candlepower, and in the case of side and tail lights, not to exceed four candlepower. Some little discussion was engendered by the recommendation for Eddi-Swan base sockets, on the ground that they are useful for only two-wire systems, whereas the tendency toward single wire systems already has manifested itself and may in time become general. It was patiently explained to the member who made the objection, however, that inasmuch as the filament of every lamp must needs have two terminals, it made no difference what style socket was used, or whether the system was single or double wire. The preference for the Eddi-Swan base socket was due to its almost universal adoption by railway Pullman car manufacturers, whose products are subjected to much hard usage, it was explained, and for no other reason.

The report of the Data Sheet Division, Cecil P. Poole, chairman, also called forth slight discussion and several suggestions of a very valuable character. The work of the committeemen was commended and their activities in getting the sheets into their present form was praised. In view of the fact that no small number of manufacturers have within the past few months sent out much valuable material in the form of sheets suitable for inclusion in the S. A. E. binder, it was suggested that the manufacturers submit the "copy" for such sheets to the Data Sheet Division first, for revision and editing and classification, so that they might be included in the index and thereby be made of immensely more value. It also was suggested that manufacturers date their sheets as issued, in order that superseded sheets easily might be located and removed. Another suggestion which was made was that whenever data collated from technical papers and magazines was incorporated in the sheets, the name of the publication, the date, and, in fact, complete information be given, in order to facilitate the location of the authority for the data. All of these suggestions the committee has under advisement, and will act upon insofar as they see fit.

The report of the Truck Standards Division, of which William P. Kennedy is chairman, was another that called forth discussion. David Ferguson, of the Pierce-Arrow Motor Car Co., criticized very severely the schedule of truck speeds, which has been adopted by the N. A. A. M. and (so he thought) the S. A. E., his contention being that to operate a 5-ton truck at 8½ miles an hour, which is the speed recommended by the N. A. A. M., is nothing short of foolish, and in his opinion can not profitably be done. He said that his company was operating 5-ton trucks, and had been doing so for 18 months, at 13 miles an hour, with markedly excellent results, and that he saw no reason for recommending lower speeds. Afterward it was explained to him that the S. A. E. has recommended or adopted no specific speeds, though speeds even lower than those recommended by the N. A. A. M. have been tentatively suggested. As regards the standardization of wheel sizes, Ferguson further remarked that because it was impossible to apply the particular make of tire which his company uses to the S. A. E. standard wheel, his truck wheels were not built according to S. A. E. standards. This also was explained by Kennedy, the chairman of the committee, who stated that

HOW SOME MEMBERS AMUSED THEMSELVES—THE KITE THAT WOULD NOT FLY

it was not the purpose of the committee to standardize either the felly band, to which the tires are attached, nor the method of attaching the tires. The purpose was merely to standardize the external diameter of the felly band, in order that tire manufacturers could stock tires which are of standard size and therefore may be applied in the shortest possible space of time. Already, Kennedy added, wheel makers have commended the action of the S. A. E. in standardizing wheel sizes, which, he said, had in one instance permitted one wheel manufacturer to stock wheels in advance and thereby release a matter of $10,000 for other purposes.

Very little discussion was brought out by any of the other reports rendered, the exception being the report of the Miscellaneous Division, which, among other things, has recommended certain sizes of rod ends and yokes for preferred practice. Though some slight objection was raised to the standards which have been adopted on the ground that insufficient bearing surface was provided, the concensus of opinion appeared to be that the bearing surface was adequate for all present purposes.

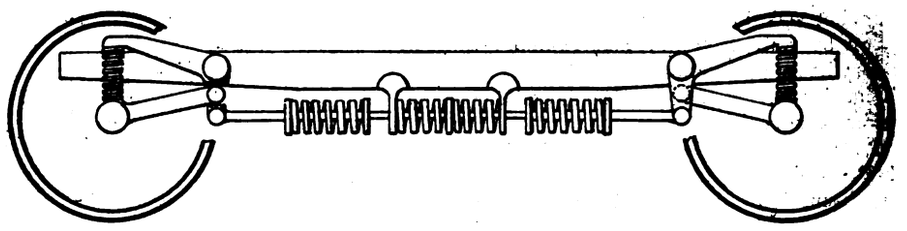
Of course the topic of standardization, brought up by Henry Souther's paper, entitled, "The Standardization Work of the Society of Automobile Engineers," was the one which caused the greatest amount of discussion. The paper, however, was largely a reply to those who have been insistent in their demand for an authoritative statement as to exactly what the society is doing and intends to do in the nature of standardization, and was a masterly portrayal of the situation in its every phase. Subsequent to the reading of the paper, which required upward of an hour, the opinion was general that the paper was timely, inasmuch as there always has been more or less trouble and dissatisfaction over the efforts of the Standards Committee. So completely did Souther cover his subject, however, that there really was very little left unsaid, and consequently there could be little discussion that was of an illuminating characted. There was no lack of speakers to add thoughts to those expressed by Souther, though they were largely in the nature of commendations for the completeness of the paper and the exhaustive manner in which the subject had been treated.

The papers that caused by far the greatest amount of discussion and which were productive of real results, were those by Herbert Chase (A Comprehensive Motor Test) and Herbert L. Connell (Standardization and Co-operation in Motor Testing). As Chase's paper was inordinately long and full of charts, and as it already had been published in the May issue of the S. A. E. Bulletin, it was not read at length, the author being content to read extracts from it and to call attention to certain other portions which he deemed of prime importance. Connell's paper was read in its entirety and proved to be upon a subject which for a considerable time has been uppermost in the minds of not a few of those present. Because the time was getting short and because of the character of the two papers, which were upon closely related subjects, it was directed that discussion include them both insofar as was possible.

The principal point that was raised in Chase's paper concerned the carburetter. David Ferguson pointed out that in the results of the tests, a slightly greater maximum horsepower had been obtained though the thermal efficiency of the motor and the fuel economy was comparatively low. This, he suggested, probably was due to the fact that the motor was tested with a carburetter other than that which had been developed for and on the engine. He suggested that very probably better all around results and greater efficiency might have been shown provided the carburetter developed for the engine had been used in the tests. Very much the same view was held by Robert W. A. Brewer, a visiting member

Digitized by Google

from England, who called attention to the fact that the percentage of air in the mixture was lower than usually is the case, and suggested that whereas only some 14 per cent. of air was used, the better proportion to use in order that the percentage of free oxygen as revealed by analyses of the exhoust gases, might be decreased in the burned products, would have been approximately 18 per cent.



In the discussion which followed the reading of Connell's paper was revealed the state of chaos which obtains as regards methods of making engine tests. It was the concensus of opinion that the standardization of some form of motor testing would materially benefit the industry in general, inasmuch as no two manufacturers at present work along the same lines, and the results are far from being comparative. The horsepower rating, as obtained by the old A. L. A. M. formulæ or the revised S. A. E. formulæ was known to be inaccurate and misleading, though up to the present time no more suitable formula had been developed; nor was it likely that a more suitable formula ever would be developed. There was no general understanding of exactly what a comprehensive motor test should embrace. Even the schools and technical universities often were at a loss to lay down lines along which to work. If the S. A. E. could standardize a form of motor testing, it was pointed out, it would not only form the basis of proper tests, but the results then would be comparative. Similarly the work would be of immense value to the individual manufacturer whose plant was not equipped for making motor tests, for the reason that he then could have such tests as he desired undertaken at the well-equipped laboratories which are available at the various colleges. That there is need for standardization of such tests there was little reason to doubt, and that there was a similar need for a basis upon which colleges and technical schools could work in making proper tests—tests that would be of value for comparative purposes—was practically certain.

It also was brought out in the discussion that there is a crying need for a properly equipped testing laboratory in the vicinity of Detroit—a laboratory that shall be equipped not only for making motor tests, but for testing the strength of materials and for fractional distillation of fuel, and the testing of lubricants, and every other matter which at present is undertaken only by the government or by technical institutions. Already one manufacturer had laid plans for such a laboratory for his own private uses and had made an outlay of some $10,000 for a site and equipment.

As a result of the discussion it was suggested that the S. A. E. look into the matter with a view to ascertaining the views of manufacturers as to the practicability of establishing such a laboratory from a fund to be contributed by them, the whole venture to be under the direct supervision of the S. A. E., and the laboratory to be in charge of a competent man. tI was regularly moved and seconded, and unanimously voted, that a committee be appointed to ascertain the views of Detroit and other manufacturers with regard to the proposed plan, which, it is hoped, will be so laid as to encourage the manufacturer who already has made arrangements for the establishment of a laboratory, to turn it over to the S. A. E. as a nucleus for the proposed S. A. E. laboratory.

Novel Australian Spring Suspension.

Australia has not been very conspicuous heretofore, so far as the rest of the world is aware, in the evolution of improvements in motor cars, possibly because the strenuous occupations of sheep raising and kangaroo chasing leave the inhabitants little time to devote to mechanical pursuits. Recently, however, there has come from the big island in the south news of an automobile spring suspension system that is sufficiently radical to make up for a great deal of the inventive backwardness of the past. Not only is the arrangement of springs and levers somewhat startling, but the results of the tests made have been such as to call forth favorable comment from men whose opinions are worth while.

CHARLEY SPRING SUSPENSION SYSTEM IN DETAIL

As the accompanying illustration shows, there is an entire absence of leaf springs in the system, all the springs being of the helical type and all working under compression. By virtue of the lever action, which for all its simple appearance is decidedly complex when it is analyzed, the weight of the car is divided among the various springs. Not only is the downward tendency of the body, as when the car wheels drop into a hole, checked by the spring arrangement, but the rebound is caught, cushioned and killed.

The device is being exploited by the Charley Taxi and Car Co., of West Melbourne, Australia; the company has constructed a car embodying the novel cushioning device and has made demonstrations that were of extraordinary severity. The machine is equipped with solid rubber tires, so that all the credit for the meritorious work done could be given to the suspension.

Los Angeles Christens the Perfex Car.

For some reason automobile manufacture has not flourished on the Pacific Coast, several factories with ambitious plans having ceased to exist in Los Angeles after more or less troubled and unprofitable existence. Despite the fact, James Fouch is the moving spirit in a newborn enterprise of the sort which is conducting operations at 126 East Jefferson street, Los Angeles, where his first car, styled the Perfex, was turned out last week and christened with considerable ceremony with a bottle of Owens River water by an official of the Los Angeles Chamber of Commerce. The car is the first of a run of one dozen which now is in process of manufacture. Fouch, who apparently is trading as the Perfex Co., states that several wealthy Easterners, among them Paul Brown, a New York stock broker, are interested in his new venture.

Nine Arrests Follow Factory Thefts.

When John O'Connell, a former employe of the White Co., of Cleveland, O., was arrested charged with the theft of goods, principally tires, from the factory, the company little expected the case would lead so far as to involve other employes and numerous garage men about the city; but when O'Connell undertook to testify before the grand jury the loophole in the stock was discovered and the method of disposing of the stolen goods was revealed. As a result, the grand jury indicted eight men for receiving stolen property, as follows: L. Herman, manager of the City Auto Livery Co., two tires, valued at $50; L. J. Converse, 228 Rozelle avenue, East Cleveland, proprietor of a garage at 1719 Euclid avenue, four tires, valued at $100; Mark Russell, cashier of the White Co., two tires; Henry Ryer, 863 East 79th street, night watchman at the White Co., two tires; John Hantack, Auto Livery and Garage, 3211 Prospect avenue S. E., two tires; Herman Holl, grocer, 6811 Clark avenue S. W., two tires; Herman Kruger, 4075 East 78th street, four tires and four casings, and Harry Osgood, chauffeur, City Auto Livery, two tires.

Exploding Air Tank Wrecks Building.

Exploding under the high pressure maintained, a compressed air tank, used in filling automobile tires, blew up Friday, June 28, in the second story of the Eureka Garage, St. Nicholas avenue and West 122d street, New York City, and tore a hole in the roof, breaking windows and causing other damage. The tank was thrown fifty feet across the room by the force of the explosion, struck an elevator shaft and rebounded, wrecking an automobile. The fire department was called out, but was not needed. Four men who were at work in the room escaped injury.

HUDSON "37" SUCCESSOR OF "33"

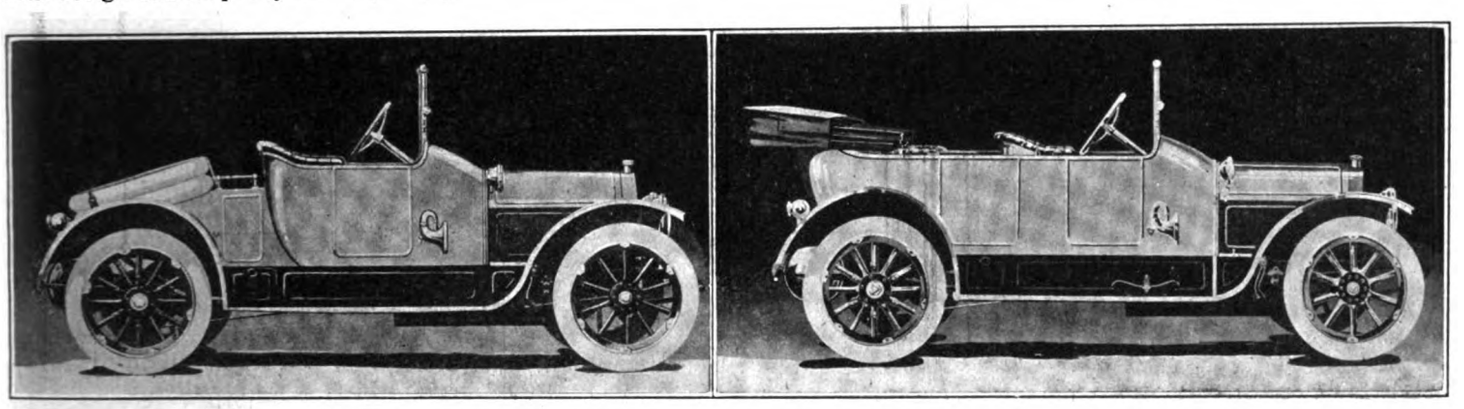
Long Stroke Motor and Electric Lighting System Features of New Model—Clean Design Remains a Characteristic.

Retaining the general characteristics of the 33 horsepower model, which it replaces, but at the same time embodying several improvements in matters of detail, a new Hudson, designated model 37, has taken its position as the central figure of the Hudson Motor Co., of Detroit, though its standing doubtless will be disputed by the six-cylinder model, which is well in hand but which has not yet made its formal bow to the public, so to speak.

Like its predecessor, the "37" derives its designation from the horsepower rating of the motor, and like the "33" it retains the clean design and simplicity which are Hudson characteristics. In order to increase the horsepower from 33 to 37, the bore and stroke have been raised from 4 x 4½ to 4⅛ x 5¼, thereby bringing the motor into the true long-stroke class. The additional power and the slight increase of size that goes with it are accompanied by slight constructional differences throughout the chassis, notably in the wheels, which have been increased in diameter from 34 to 36 inches, and in the brakes, which, formerly 12 inches in diameter, now are 14 inches.

Perhaps the most conspicuous new thing is the built-in Delco electrical system for ignition, lighting and motor starting, the motor-dynamo which forms the chief part of this apparatus being bolted to the right-hand side of the engine, as shown in the accompanying illustration of the power plant. The dynamo is driven from the flywheel, on the rim of which gear teeth are cut, meshing with the shaft pinion of the dynamo; the machine, used as a motor for starting, of course drives the engine through the medium of the same agency. The Delco system takes care of the ignition, which is of the dual type, the illumination and the motor starting, with the addition of a dry battery for emergency ignition use.

Silent running always has been a feature of Hudson cars, and though it would seem as if there was not a great deal of room for improvement in this direction, the trend of the trade has been followed in further eliminating noise. Many factors contribute to the much-desired quality of quietness. The valves are operated by push-rods that have large bearing surfaces, ensuring a close fit and lack of the lost motion that means noise; the covering plates over the valve stems shut in the slight clicking of the tappets on the stem ends, as well as protecting the working parts from dust. The timing gearing, which in many motors is a prolific source of racket, in the Hudson motor is of the worm type, running in oil, and there is an entire absence of sound from this part of the mechanism. With springs that do not squeak or rattle, accurately cut gears in the gearbox and the rear axle, close fitting of parts throughout the car and an efficient muffler, there is very little chance for undue noise.



While the Hudson "33" is a comfortable and easy riding car, largely because of the long, flexible springs and the correct hanging of the body on them, the new car has gone a step further in this matter also, and by the two-inch increase in wheel diameter, bringing the wheels up to 36 inches, and the fitting of 4 inch tires in place of the 3½ inch pneumatics formerly used, to say nothing of the effect of upholstering that is no less than 12 inches deep, the Model 37 has been made even more comfortable.

The controlling system, which has been changed in details only, is composed of the usual two side levers, on the right hand side, for the change gears and the emergency brake, a pedal for the clutch, another for the service brake, and the throttle and spark levers on top of the steering wheel, remaining stationary when the wheel is turned. The steering wheel is no less than 18 inches in diameter, and operates through the medium of a worm-and-sector mechanism which is noiseless and, of course, irreversible. The side levers are carried inside, thus maintaining the smooth, clean outward appearance of the flush-sided bodies.

The principle of the unit power plant system that was employed in the 33 horsepower car, with the motor carried directly on the main frame by a four-point suspension, is retained, with the block-cast cylinders, centrifugal water pump, three-speed selective gearset and disk clutch with cork inserts in the flywheel. The use of the new starting system, however, has necessitated some motor changes, such as the placing of the intake manifold on the left side with the exhaust manifold, and the removal of the pump from the front to the right side of the motor. The lubrication system is of the constant level splash variety, the oil level being maintained by a force-feed pump driven from the camshaft. Though both intake and exhaust manifolds are on the same side, they can be removed without either interfering with the other. Valve stems are enclosed, as heretofore, and the motor—and, for that matter, the whole car—is notable for its extremely quiet running, as is the older and less powerful car.

To the rear of the power plant changes have been made also. In place of the steel tube enclosing the propeller shaft, there is a torque arm, of pressed steel, to the right of the shaft, the shaft itself being bare. The torque arm has the usual double spring buffet mounting at the forward end. Drive is directly through the three-quarter elliptic rear springs, which are 50 inches long and 2 inches wide, with a large number of thin leaves—an arrangement that is more conducive to easy riding than a smaller number of thick leaves. All the leaves are of the tongue-and-groove type, to prevent lateral misplacement, and are assembled with graphite between them to avoid squeaking and to give the readiest possible action; the eyes are bushed with bronze. From the more usual place under the front seat the gasolene tank has been moved down to the rear of the frame, where it is supported by heavy brackets and leather lined steel straps. An air pump driven by the camshaft provides the pressure for feeding the gasolene to the carburetter. The tank, which is of pressed steel, is tested under pressure to guard against leakage; it is provided with a gasolene guage, mounted on the top, and with a drain plug at the bottom.

The new Hudson chassis carries roadster and touring bodies worked out in straight

NEW HUDSON MODEL 37 WITH ROADSTER AND FIVE-PASSENGER TOURING BODIES

Digitized by Google

lines and short curves in a manner that is decidedly pleasing to the eye. The flush sides, clean running-boards and skuttle dashes all contribute to the simple, unencumbered appearance of the cars. The equipment supplied, apart from those items, such as starting device, gasolene gauge, etc., that are built in and therefore practically integral parts of the car, consists of electric head, side and tail lamps, interior dash lamp, an extension lamp that can be plugged in at several places, avoiding the inconvenience of an extremely long cable, magnetic speedometer with keyless clock, an extra demountable rim, tire holder, windshield, mohair top with curtains and dust cover, tools, tool box and license holder. The tool set really is a tool set, as it includes files, pliers, extra wrenches, hammer, punches and everything that is likely to be needed in the course of ordinary service.

The finishes are regularly in Richelieu blue, with chassis, hood, fenders and wheels blue-black. Pearl gray body finish is given as an option.

Gasolene Loop that Prevents Trouble.

When a gasolene feed pipe is looped or otherwise bent in order to avoid the rigidity and liability to breakage of a straight pipe, air locks and consequent interruptions of the flow of fuel are likely to occur after filling the tank unless sufficient gasolene is poured in to produce the pressure required to drive out the air that will be trapped if the loop or bend is made in a vertical plane. If the loop is turned so as to lie horizontal, however, there will be no such trouble. Incidentally, a complete loop is the best safeguard against crystallization and consequent breakage of the pipe.

Beeswax to Prevent Rusting of Rims.

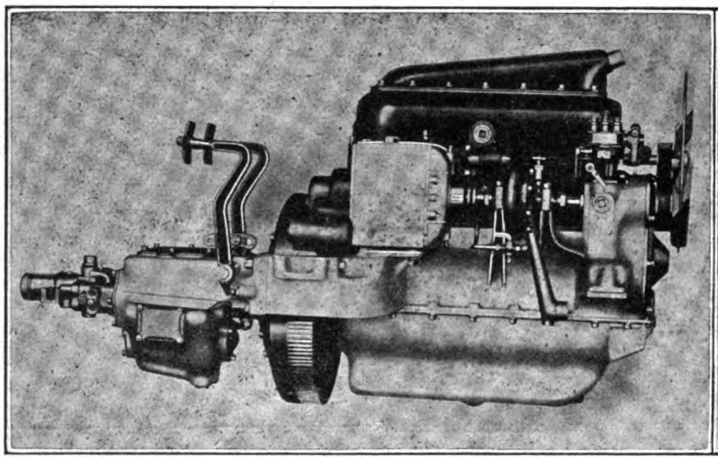
The rims of automobile wheels will, even though they have been well painted, rust in time, and the rust will cause excessive tire wear. If the rims are heated by means of a blow torch and a coating of beeswax applied, the further formation of rust will be prevented, for the wax and rust will form a hard compound impervious to water.

INCREASE POWER BY FUEL PUMP

Old Device to Gain Maximum Motor Efficiency Resurrected Abroad—Complication That Offsets Advantages.

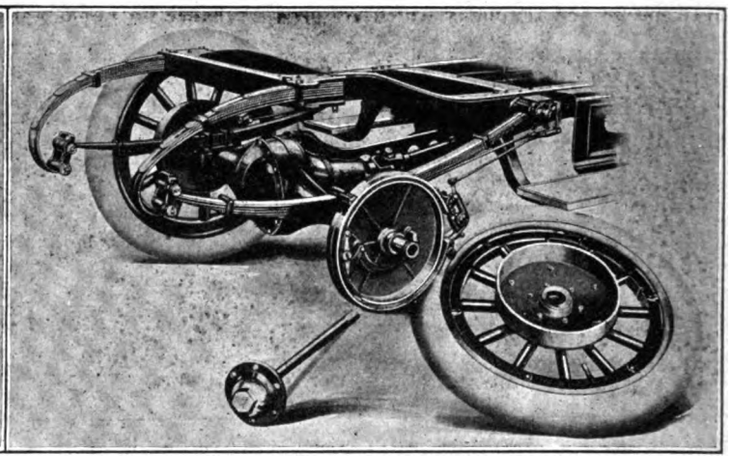
In the desperate struggle in which some of the foreign motor manufacturers are engaged in the effort to obtain the greatest possible power from a motor of a given size and weight, all sorts of ingenious expedients are resorted to—and usually abandoned after a few trials. One of the latest, which, however, is old in principle, is of European design and involves the use of two pumping cylinders, one for each two of the four cylinders of the motor. The two extra cylinders are placed at the front of the motor and are driven from the crankshaft; connection is established with the working cylinders through suitable ducts and valves, the valves being in the intake valve chambers just above the service valves. The system also involves a rotary distributer.

The working cylinders draw their charges from the carburetter in the usual way; at the same time, the auxiliary cylinders draw combustible gas from the same source. When a working piston has reached the end of its intake stroke, and the cylinder is full of gas, the auxiliary valve opens and one of the pumping cylinders forces in an extra charge of mixture under pressure, so that the material available for explosive purposes is considerably in excess of the normal. Quite naturally, the force of the expanding charge when ignited is tremendous. But the pumping cylinders have a further duty. At the end of the exhaust stroke the auxiliary valve opens again, and the cylinders are scavenged with mixture from the carburetter, so that not only do the working cylinders receive more gas than they are entitled to, so to speak, but there is no dilution of the mixture with burned gas left over from the previous explosion.



It goes without saying that the fuel consumption of this motor is very high; but as the idea was to obtain power, the question of fuel economy was relegated to the background. It is said that the noise of the exhaust of this engine is something terrific—which, of course, is what might be expected—and that the power obtained is considerably in excess of what had been developed by other motors of similar cylinder capacity. There are, however, very decided limits to the results obtainable from an expedient of this sort—for instance, the limit of compression without pre-ignition has to be considered. While the experiment is interesting, it hardly is to be expected that its results will be of much practical value because of the extra complication.

Fixes Rate of Hire for Cars per Hour.



While the use of an automobile for political purposes often has been regarded as financially profitable to a high degree, the motor car liverymen of Indianapolis have been given a jolt by a judicial decision adverse to Frank P. Cox, who had billed his car's services at $4 an hour for carrying Democratic voters to the polls at the recent primaries. Fox sued Thomas S. Meeker, who had contracted for the cars, and the defense was that $4 an hour was excessive. Judge Clarence E. Weir of Superior Court readjusted the bill, allowing $3 an hour, which he declared was quite sufficient, and allowed Fox a total of $149.50 for toting the balloters.

Kankakee Limits Taxicab Charges.

While New York and some other of the larger cities of the country are wrestling with the taxicab fare probem certain smaller towns are going ahead and fixing rates for the motor cabs, and the rates, once fixed, are enforced. Kankakee, Ill., is the latest to add itself to this list, and has made rates as follows: From depot to depot, one person, not to exceed one mile, 25 cents; exceeding one mile, 50 cents; for each additional member of the party, 25 cents; no charge for children of party under five years of age.

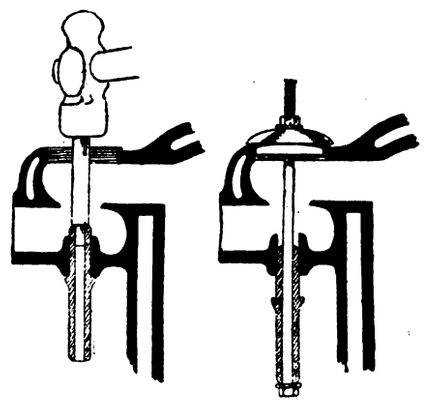
WORN VALVE STEMS ROOT OF EVIL

Obscure Source of Trouble Often Reflects on Innocent Carburetter—Remedies Other Than Replacement.

All carburetters are more or less good and, similarly, all carburetters are more or less bad; there is not one that has no good qualities, but it remains for future generations to evolve carburetters innocent of all evil. No matter what view of the matter may be taken, however, there is no doubt whatever that a great many carburetters are given credit—or discredit—for failing to perform their mission, when the aspersions should be cast upon some other vital part of the power plant, which, nevertheless, escapes notice for reasons that vary with the character of the parts concerned. Troubles resulting from faulty ignition are not infrequently visited upon the unoffending gas-maker; leaks in the intake connections often give distressingly correct imitations of carburation evils; and last, but not least, though usually most unsuspected, worn valve stems cause the motor to misbehave very much as though the carburetter was doing those things that it ought not to do, or failing to do those things that it obviously ought to do.

The logic is simple enough. When a valve stem or its guide is worn—and it is the stem—nine times out of ten, rather than the guide—there is an opening made through which unwelcome air can find ingress, under the urgent suction of the piston; the mixture that goes to the cylinder is diluted more than it really ought to be, and more or less abnormal action takes place, according to the extent of the dilution. If the proportion of air admitted in this underhand way was uniformly in proportion to the volume of the mixture, and was the same for all cylinders, matters would not be quite so bad; but naturally the greater the suction the larger the quantity of superfluous air admitted per charge of mixture and, as the partial vacuum is greatest when the throttle is partly closed, it follows logically that there will be more trouble due to diluted mixture at low and medium than at high speeds. The lower the speed the greater the quantity of gasolene must be mixed with the air in order to adequately enrich the air; if, therefore, the carburetter is so set that the engine runs as well as it can be made to run at the lower rates, it will run badly at higher speeds, consuming an excessive quantity of fuel per mile and tending to produce carbon deposits and heat up the engine.



Of course, the extent of the trouble will vary with the amount of wear of the valve stems, and may amount to anything from an occasionally mysterious miss to a thoroughly unruly functioning of the motor. Not only is there lack of uniformity of the super-auxiliary air supply at different speeds, but as the different stems are likely to wear at different rates there is a probability that the unostentatious but very industrious extra air inlets will so vary in their evil capacities that no two will admit just the same volume of air, so that a carburetter correction that would help things, so far as one cylinder was concerned, might have just the opposite effect on other cylinders. In many instances the effects of leaky valve stem guides are sufficiently like carburation troubles—so much so that

FIGS. 1 AND 2

even those who might be expected to know better often are deceived, and it is not at all uncommon for a carburetter expert to fail to make a correct diagnosis.

Worn stems are not by any means peculiar to inlet valves; exhaust valves are in the same class, in this respect. The effects are different, however, for instead of atmospheric pressure from without, as in the case of the inlets, there is pressure from within—that of the exhaust, hot from the cylinders and seeking exit. If there is a

FIGS. 3 AND 4

narrow passage along an exhaust valve stem, the eager gas does not neglect the opportunity, and a sizzling hot little streak will follow along the channel, heating up the stem, burning away and carbonizing the lubricating oil, if there happens to be any present, and, finally, blowng out upon the valve spring which, in case of a bad leak, might be softened and its usefulness destroyed in a way that would appear nothing short of mysterious.

The evil having been hunted down, it remains to provide a remedy. Heat, particles of carbon and the difficulty of adequate lubrication make it extremely hard to do very much to mitigate the conditions under which the exhaust valve stems work; but there seems no really good reason why the intake valve stems should not be protected. The accompanying illustrations, from the "Auto-Motor Journal," indicate how such protection may be added to valve mechanism of the ordinary type. In Fig. 1 is shown the simplest method, which consists of placing over the lower end of the valve guide a brass cap containing a felt washer, both cap and washer having holes through which the valve stem passes, as snug a fit as possible without binding. A helical spring, small enough to go inside the valve spring without touching it, rests against the spring washer on the valve stem and holds the brass cup and its washer against the end of the guide. Before being put in place the washer is soaked in oil and dipped in flake graphite. A few drops of oil a couple of times a week will keep the valve stems thoroughly lubricated; and while the primary purpose of the arrangement is to provide lubrication, it also acts as an efficient excluder of dust, much to the benefit of the valve stem. In the case of valve springs that are too small in diameter to permit the use of the arrangement shown in Fig. 1, a cap can be made like that shown in Fig. 2, which works on the same principle but is of smaller diameter and a little deeper. It is held in place by three or four brass fingers extending upward and pinched between the top of the spring and its seat on the cylinder casting. Both these devices are easily made and even more easily applied, and are extremely beneficial in their effects. They are of no use, however, if a valve stem already has been badly worn, for while further wear might be checked somewhat and leakage decreased, the only real remedy is a new valve or a new guide—or both, according to the conditions.

In removing a valve stem guide difficulty occasionally is experienced because the guides, which commonly are pressed into the cylinder castings, sometimes fit so tightly as to refuse to move without the application of considerable force. The proper way to remove a guide is to drive it with a hammer and a piece of brass or copper, as shown in Fig. 3. The soft metal is useful because it prevents the burring of the end of the guide, which might prevent its pasasge through the opening If the guide is to be used again there will be a double reason for using the soft driver. If the guide is so tightly fitted as to resist a few fairly sharp blows of the hammer, it can be persuaded by heating the cylinder by circulating hot water through the jackets until the iron surrounding the guide is so hot that the hand cannot be held on it, pouring cold water through the hole in the guide for about fifteen seconds and then quickly using the hammer and soft driver. The combined expansion of the casting and shrinkage of the guide will make the task an easy one. Once in a long while a motor is found in which the guides are screwed in.

Digitized by Google

In such a case it is obvious that no amount of hammering or of alternating heating and cooling would do any good—except that the latter process might be useful in case the threads had been screwed up very hard.

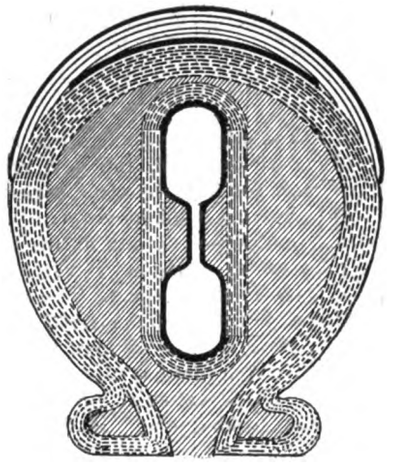
In putting in new valve stem guides care should be exercised not to burr or deface the metal; and though, of course, the hammer and soft driver—or, better yet, a block of hard wood—can be used, a better way is to make an appliance such as is shown in Fig. 4. This is simply a long bolt fitting snugly in the valve stem guide, with a head to keep it from pulling through. The opposite end is threaded and is passed through a yoke or cap on the top of the valve chamber. By screwing down the nut the guide is pulled steadily and truly into place without danger of breaking or burring.

The application of lubricating caps to valve stems already much worn is merely an excellent illustration of the old saying anent the securing of the stable door subsequent to the departure of the equine occupant; but applied to valve stems in good condition, these little lubricators will keep the stems in good condition for a surprising length of time.

Tiny Hammer of Enormous Power.

The sclerescope, an instrument which tests the hardness of metals by means of a little "tup" or hammer which is allowed to fall on the surface to be tested, is a rather remarkable example of the application of a simple principle. In testing metal by indenting the surface, which is one of the methods employed, it is necessary to apply the equivalent of enormous pressure. To indent hardened steel, for instance, requires a pressure of something like 500,000 pounds per square inch; yet it is done, in the case of the scleroscope, with the little tup hammer, the weight of which is only 40 grains. The secret of this seemingly impossible feat is that the area placed under pressure by the hammer is exceedingly minute, being 1-5,000th part of a square inch, and this is so small in comparison to the weight of the hammer that the pressure on it, slight as it is, is sufficient to make a microscopic pit. Of course, as the area is 5,000 times less than a square inch, the pressure required is 5,000 times less than that required to indent a square inch, or 100 pounds, which is the striking force of the little hammer.

When Battery Jars Begin to Bulge.



If through excessively rapid charging or discharging a battery becomes so heated that the rubber jars begin to bulge, they should be supported at the sides, if possible, until they have had time to cool and harden again. Usually it is very difficult to do this, but if it can be managed much trouble may be saved. Owing to the mass of solid metal and the volume of liquid heated up to a high temperature, the cooling process takes considerable time, and if the jars are badly softened there is much danger of their destruction.

"PNEUMATIC" TIRE MINUS AIR

Brooklyn Inventor Makes Startling Use of Vacuum Principle—Air Pumped Out of Instead of Into Tire.

Since pneumatic tires first were fitted to wheels, and their superiority in point of resilience over solid rubber tires demonstrated, many, many attempts to so improve the air tire or to supplant it with a tire equally as resilient, yet free from the possibility of rupture which renders the tire useless for the time at least, have been suggested, tried, advertised, sold, and discarded as incomparable with the air filled tire in easy riding qualities.

The trouble with all of the substitutes, according to the views of Willard J. Woodcock, of 102 Gates avenue, Brooklyn, N. Y., who just has perfected and placed on the market a tire which is radical from the letter "r," is that the elimination of the air limits the elasticity of the tire to a point within the elastic limit of the substance of which the tire is constructed, so that a tire which depends for its easy riding qualities on the compressibility or extensibility of solids never can compete with the pneumatic, since air has no elastic limit.

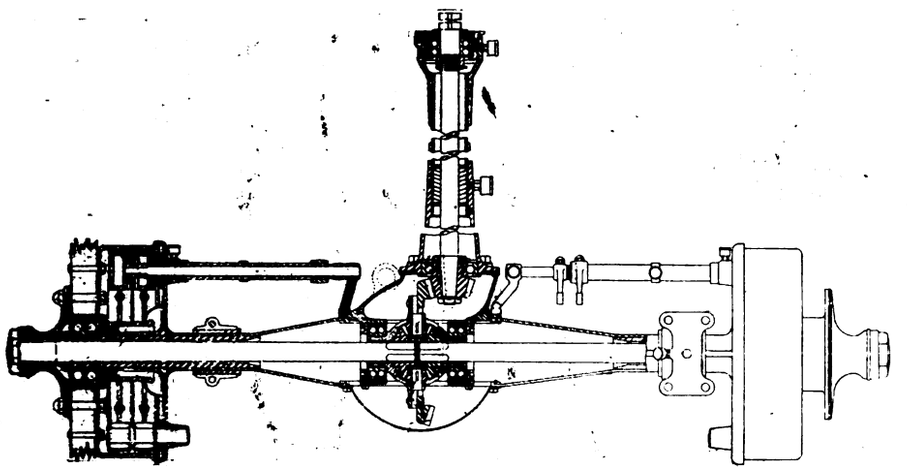
WOODCOCK "VACUUM" TIRE

With these principles in mind, Woodcock has evolved what he terms a Single Tube, Wrapped Tread, Vacuum Tire, a cross-section of which is shown in the accompanying illustration, the innovation being that the air is pumped out from the interior by means of a suction pump instead of being compressed into it, as is the case with orthodox construction. The air chamber, or it might better be termed the vacuum chamber, for very little air remains after the pumping operations have been completed, is half an inch wide and two and seven-eighths long when no pressure is exerted on the tire other than that of the atmosphere. When the weight of the car is applied, however, the chamber tends to widen in the middle and this tendency is resisted by the pressure of the atmosphere which is exerted on the outside of the tire. Thus, according to the maker, the vacuum tire, like an ordinary pneumatic, depends for its resilience on the elasticity of the air, and yet blowouts are impossible, for the pressure is all external and the fabric is not strained. Punctures, although not impossible by any means, need not necessarily occasion delay, for sufficient rubber is embraced in the construction for the tire to be used as a cushion tire, even when entirely "inflated." The heating effects, too, are not so much in evidence, for the rarification of the air, as each shock is encountered, tends to keep the tire cool. The tires are at present made in two sizes only—34 x 4 and 35 x 5½, but the inventor hopes to be able to supply them in all stock sizes to fit Q. D. rims within the next few weeks.

Evidence Affecting Electric Starters.

Although there are those who are disposed to fight shy of electric lighting and electric motor starting systems because of their seeming complication, and because of lack of general understanding of electrical principles, firsthand evidence obtained by the Cadillac agency in New York during the past several weeks is of the sort to show that not only there is little room for scepticism but that the electric device has reached a state of reliability that is not to be denied. In order to satisfy itself, and to secure the information, the Cadillac agency addressed inquiries to some 500 users of Cadillac cars fitted with the Delco Electric system, asking, among other questions, how often it had been necessary to use the starting crank and for what reason. Of 67 who replied, and who represented a total travel of 208,489 miles, but six reported having used the crank and the necessity therefor was, in each case, of a trivial nature. In two instances, wires had become disconnected, in two others, dirt or grease had affected the connection and in the others a loose connection and a rod which required adjusting were the causes of the failure of the electric system to fail to perform its mission.

Increasing Efficiency of Aluminum Cells.



The aluminum cell, which consists of a plate of aluminum and a plate of either iron or lead immersed in an electrolyte consisting of bicarbonate of soda dissolved in water, has long been used as a rectifier for alternating currents, the chief drawback being the comparatively low efficiency—under 50 per cent.—of the apparatus when the cells are connected up in the ordinary way. The efficiency, however, can be greatly increased if the cells are connected as shown in the accompanying diagram, the connections being such that instead of totally killing one impulse and allowing the others to pass, the cells permit both impulses to pass, but "switch" them so that a continuous current is available at the D. C. terminals. The only losses are caused by the high resistance of the electrolyte, and are dispersed as heat.

MASTERS LIVE AXLE DIFFICULTIES

Michigan Manufacturer Produces Improved Mechanical Unit—Attention Paid to Brakes Which Are Cam-operated.

The popularity of shaft and bevel gear drive, which has reduced the number of chain-driven cars to a small minority, has created great opportunities for the manufacture of live axle units by concerns which specialize in products of this class; of whom few, if any, are better known than the Weston-Mott Co., of Flint, Mich., which just has added a rear axle of that type to its line. Owing to the complexity of the rear axle unit, its many moving parts, the difficult gearing and driving problems involved and, last but not least, the fact that

CONSTRUCTION OF NEW WESTON-MOTT REAR AXLE

all the power delivered by the motor and the greater part of the weight of the car must be transmitted through the live rear axle, the production of a really good rear axle is a matter of no small engineering difficulty. How the new Weston-Mott axle meets the problems involved is made plain by the accompanying illustration; while, of course, the axle follows standard lines in its general design, it involves not a few details of special interest.

The housing, which is the foundation upon which everything else in the axle depends for stability, is of pressed steel; its manufacture is facilitated by the fact that it is made in two parts, which are welded together by the oxyacetylene process, so that the finished housing is, to all intents and purposes, a single piece. Special attention has been given to the brake question, with the result that there are two internal expanding brakes, working side by side on the same drum, and not only are they thoroughly enclosed and protected from dust, but special provision has been made for the ejection of any oil or grease that may work through along the shafts. The brake bands are each 1¾ inches wide and 15½ inches in diameter. The illustration shows quite clearly the arrangement of the brakes and their drums, the latter, of course, forming the main portions of the protective coverings and the inner ends being closed by a cap which is formed integral with the outer end of the main housing. The brakes are operated by cams which, when partly rotated on their shafts, force the bands to greater diameter and press them against the drum surfaces. The shaft of the cam nearest the wheel—that is, the outer cam—passes through the tubular shaft of the other cam. The arrangement is clearly shown.

It will be noted that there is a curved piece on the inside of the inner cap of the brake drum, quite close to the center. This forms an annular chamber into which must pass all oil that works through from the center of the axle. The shape of this chamber is such that the oil cannot escape and get on the braking surfaces unless it should overflow the annular space, and this is made impossible by the employment of an escape pipe which drains out oil as fast as it finds its way in.

The bearing at the small bevel pinion of the main drive is of the annular type, with a single row of balls, and its shaft is supported at the middle by a roller bearing. Double ball bearings are fitted at all other points. The differential gear follows standard practice in that it is of the bevel type; a removable cap at the rear side of the axle gives access to the interior.

Resistance to vertical stresses is provided by forming the pressed steel housing with a deep vertical web which runs up to the full width of the central gear housing and a little more. The spring perches, of substantial construction, are secured in place by means of cap screws with long threads running into deep lugs. All bearings that are not lubricated from the central housing are provided with special grease cups.

A magneto never should be mounted on an insulating base except when so specified by the manufacturer; otherwise the return or ground circuit will be broken.

PUTTING OLD PARTS TO HOME USE

Oregon Brings Proof That "Remains" of Disused Cars Hold Great Utility—Purposes They May Serve.

That the parts of an old car can be put to many practical uses is amply demonstrated on a country place out in the Coast mountains of Oregon. While a guest at this country place not long ago, I was struck with the peculiar shape and extremely rich appearance of a "lazy seat" that occupied one corner of the host's smoking den. When a commending remark was offered regarding it, the owner, an energetic young westerner, enthusiastically replied:

"That seat is the tonneau which was formerly a part of 'Old Betsy,' the finest and toughest touring car that ever broke a Goast Range trail. Isn't it comfy?"

I assured him that it was; for the leather, despite the hard service it had given, looked almost as good as new with its repolish. The upholstering was deep, and, taken as a whole, it was much finer and richer than the average settee.

"I couldn't buy anything like it for less than one-fifty," my host assured me. "You see, I had to drive 'Old Betsy' and never rode much in the tonneau. But I'm getting my share of the fun from it now. Follow me, and I'll show you more of her." Whereupon he led me out to his "incubator house," where some three or four machines were converting eggs into pure blood White Leghorn chicks. Though it was winter, the room was comfortably warm. Over against the wall was something that looked very much like an automobile radiator. On getting closer, I saw that it was a radiator.

"That's where the heat comes from to keep this room warm," my host explained. "I formerly had considerable trouble keeping the temperature right, particularly on cold days. Now it's easy. I simply connected the old radiator with the hot water pipes from the kitchen boiler, bent all the fins together, as you will notice, and the thing was done. All the water drawn for the kitchen must circulate through the radiator; that keeps it warm—just warm enough to make the incubators work perfectly."

Nor was this all; for down in the basement of this up-to-date country place is a four-cylinder motor. It formerly was a part of "Old Betsy." Now it is connected to a small dynamo, which, in turn, is connected to a series of four accumulators, or storage batteries. And this simple electric system supplies light for the entire place. By using the accumulators the motor needs to be operated only at odd times, thus storing electricity which can be used at any and all times. Incandescent lamps of the regular motor car type are employed, these requiring less "juice" for the maximum amount of light.

Digitized by Google

Out in the barn I had another surprise in wait. It was a light-weight, single-horse truck. Though light, and exceedingly easy running, it would easily carry 2,000 pounds. This truck was nothing less than the chassis of "Old Betsy." Everything had been dismantled except the frame, springs, axles and wheels. The pneumatic tires had been replaced by those of solid rubber. A truck bed was placed on the frame, and shafts were attached to the steering knuckles.

"One horse can take a load in that truck at a full trot," said the owner. "It's the lightest running rig on the place, excepting the successor to 'Old Betsy,' and that runs itself. About the only thing that looks wrong about it is that big wart on the hind axle, which formerly served as the housing for the differential. But I preferred to let it remain just as it was, removing the differential gear, rather than go to the expense of having a straight axle made."

In the dining-room I was shown two more fine leather chairs, made from the individual front seat of the old car. "All I had to do was saw the old seat in two, and touch it up a little," the young rancher told me.

When I asked if this plan paid him better than that of selling the old car, or allowing it in exchange, he declared emphatically that it did.

"It puts me ahead of the game any way you want to look at it," he assured me. "I hated to sell the old car—turn her over to a stranger who wouldn't understand her whims. Something would go wrong the very first crack—something that I would know in a wink, and could fix in the dark—but would leave a stranger stranded thirty miles from home. No, sir! I just couldn't part with her. I thought as much of 'Old Bet' as I think of any horse on the ranch, and I couldn't bear to think of some softhead cussin' and kickin' her around just because he didn't have sense enough to savvy her language. They offered me $400 for her on exchange, when I bought the new car, and remarked that I was finding that much if I took it. I told them to keep the money, and wrote a check for the full price, brought the old girl back and dissected her. It isn't exactly 'Old Bet' any more, but I have the pieces to remind me of her, anyhow, and that's worth a good deal."

That was the sentimental feature of the thing—and, truly, was enough; but to fully convince me that he had "beaten the game," the young rancher wrote down the following, which shows each part as he now uses it, and how much that part is actually worth, or would cost:

"Lazy seat" for den	$150 00
Two dining-room chairs	100.00
Motor for private electric lighting system	220 00
Radiator for heating purposes	25 00
Farm truck	75 00
Total	$570 00

COAL TRUCK GIANT IN ECONOMY

Replaces Five Horses and Cuts Delivery Cost Nearly in Half—Rapidity of Service a Feature.

While many coal dealers—to say nothing of those who handle other commodities—have done considerable experimenting with motor trucks with a view to finding out exactly what it costs to operate them under regular service conditions, the figures obtained rarely are available for publication, for if the machine is successful the owner usually considers that his competitors are not entitled to the free use of the fruits of his experience, and if it is a failure, the less said the better. Besides these reluctant ones, there are, of course, many whose records are of no real value because of the omission of vital features. Therefore, when data compiled in the course of a period covering three-quarters of a year is allowed to leave the sacred precincts of the bookkeeping department, it is of no little interest. Spaulding & Spaulding, of Buffalo, is a firm that has made successful use of a motor coal truck and can see no reason for keeping the figures which indicate the extent of its economy in coal transportation locked up in its books. This firm purchased a Pierce-Arrow five-ton truck, with worm drive and a power-operated screw hoisting body, and the machine was put to work in September, 1911. Since its installation the truck has handled practically 8,000 tons of coal and the cost of transportation figures out at .279 cents per ton; this includes 6 per cent. interest on the investment, insurance, wages of a driver and his helper, tires, gasolene, lubricating oil, repairs, depreciation and a fair allowance for annual overhauling. As compared with horses, the motor has done the work of two double teams and a single rig, besides reducing the cost by two-tenths of a cent per ton.

The mileage covered since September was 8,093 miles, and it is stated that the fears originally felt by the owners that the tires would prove costly have proved to be groundless; the tires were in such condition on June 1st that they were credited with having another 1,000 miles of life in them.

The most important feature of the motor delivery service, from the point of view of the man who buys the coal, has been the rapidity of delivery at all times, regardless of the weather conditions that sometimes are such as to make delivery by horses a matter of the greatest difficulty, if not almost an impossibility. It is stated that this phase of the matter has brought out no little favorable comment from customers.

An important advantage of a motor truck with a power hoist is brought out in the accompanying illustration. In many cases it is necessary, owing to the arrangement of the coal holes in the sidewalks, to place the coal truck in a position that is very inconvenient for passing vehicles, and may even cause a serious obstruction in a narrow street. Where there is a power hoist it is possible to get the coal out of the truck in the shortest possible time, and this alone often effects a saving in trouble that is not always appreciated at its real value.

PIERCE-ARROW 5-TON WORM DRIVE COAL TRUCK

Improving Spark for Motor Starters.

A condenser of proper capacity bridged across the contacts of the push button supplied on the gas type of motor starter will do much toward assisting the production of a good spark. It must be remembered that in starting, the condenser which bridges the contact breaker and absorbs the back kick is ineffective, for the simple reason that the breaker terminals are closed and the condenser short circuited. The condenser across the push button, which should be of the same capacity as the magneto condenser, will not only increase the spark by relieving the back-kick, but also by causing a quicker break. Then, too, it will eliminate much of the burning to which the platinum terminals of the button are subject and which causes all too rapid deterioration.

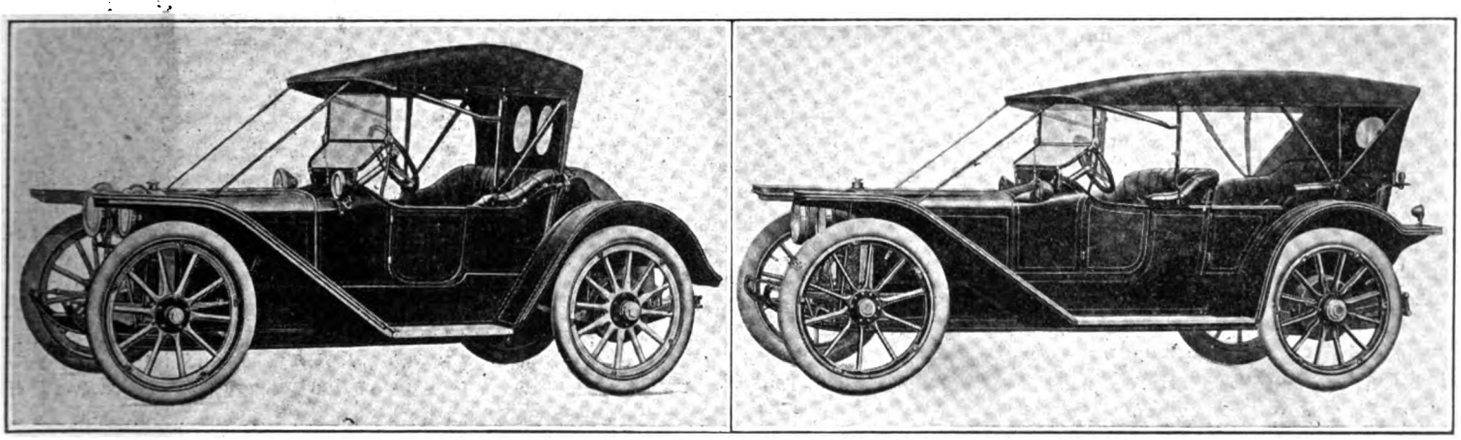
INCREASED COMFORT IN AMERICANS

Changes in Equipment Rather Than in Mechanism of Famous Underslung Line —Smallest Model Unaltered.



Since bringing out its first underslung motor car, some eight years ago, since which time the low, compact body and big wheels have become familiar sights on the road, the American Motors Co., of Indianapolis, Ind., manufacturers of the American underslung cars, have made many changes in details, though retaining always the cardinal feature of the machine—the underslung frame with its low center of gravity and easy riding on rough roads.

In the new models, however, which just have been announced, the changes are less important, from a mechanical point of view, than usual—in fact, the smallest car of the three which constitute the line, the American Scout, is wholly unchanged, while the largest, the American Traveler, shows alterations only in the line of equipment, and the intermediate model, the Tourist, which differs more than the others from its predecessor, shows only such changes as the adoption of the Eisemann dual ignition system and a new lubricating system in which oil is circulated by a pump in a sump in the bottom of the crankcase, and there is an oil indicator on the dashboard; this replaces the older self-contained splash system. The body has been widened two inches, giving a little additional room for the passengers; convenient pockets have been placed on the doors in the tonneau; a glove bag is located between the front seats, with an upholstered lid that does not break the continuity of the cushioning; deeper and softer cushions are used all round; the back of the front seat has a leather covering in which are large receptacles for the score of odds and ends that are convenient to have in a car. There is an extra inch of clearance between the front of the rear wheel and the running board, and the space between the running board and the frame has been enclosed in sheet metal. The front shackles of the rear springs have been enclosed in sheet metal housings as a protection against dirt. The tail light is of the electric type and is carried on the rear end of the left fender, while the opposite fender carries a license bracket.

The largest car has a motor rated at 50 horsepower, with cylinders of 5⅜ x 5½ inches bore and stroke, and a wheelbase of 140 inches and 41 inch wheels with 4½ inch tires on demountable rims. The new model is equipped with an electric starting device, which also furnishes current, when the motor is running, for the illuminating system. A Warner speedometer with clock, mohair top, side curtains, windshield, tools, etc., complete the equipment.

The Tourist has a 40 horsepower motor with cylinders of 4½ x 5 inches bore and stroke, 118 inch wheelbase, 37 inch wheels and 4 inch tires on demountable rims. There is a complete electric lighting outfit, with dynamo and storage battery, a motor starter, speedometer, top, windshield, side curtains, and so on.

The smallest car, the Scout, has a 3¼ x 5 inch motor rated at 22 horsepower, but claimed to be capable of developing 30 horsepower. The wheelbase is 105 inches and the wheels are 36 inches in diameter, with 3½ inch tires and demountable rims. In this model the side and tail lights are electric, the necessary current being supplied by a storage battery, while the headlights are acetylene. The rest of the equipment corresponds closely with that of the two larger cars.

REVISED EDITIONS OF TWO AMERICAN UNDERSLUNG MODELS—SCOUT AND TRAVELER

Wiring Lamps to Avoid Short Circuits.

When running wires for an electric lighting system, great care should be taken to see that none of the wires are so positioned that the sill of the body can squeeze them, for otherwise the constant chafing will soon cause grounds, which will be fatal to the satisfactory working of the system. The wires should be placed in the channel of the frame iron and retained by clips or brackets, which will prevent movement in so far as possible. To prevent "shorts," two wires should not be held by the same clip.

COLLEGE STUDIES TRUCK PROBLEMS

Verdict Favors Electric Trucks and Horse Is Not Entirely Discredited—Facts Gathered from All Services.

What the Massachusetts Institute of Technology is doing in the way of close and accurate investigation of the efficiency of motor trucks is realized by few, but these researches have a fundamental interest to the business man who is considering the use of motor trucks. These vehicles have sprung into existence with enormous rapidity, yet till to-day there has not been a real knowledge of whether they are truly well adapted to their work. To find this out the Institute has set itself to investigate and the close of the first year finds the work in such satisfactory condition that the costs of continuing the research have been guaranteed by various individuals and firms, among the former being Thomas A. Edison.

It is but natural that the funds for research of this kind should be furnished by business men, for aside from the direct approval or disapproval of a method or a device, there is furnished information that may serve to guide the business firm against mistake. So a year ago a fund was placed at the disposition of the Institute by the Edison Electric Illuminating Company of Boston, the only condition attaching to which was that every factor to efficiency in methods of trucking should be considered. The fund came naturally to the department of electrical engineering; Professor Harold Pender was given the direction of the investigation, and to research assistant H. F. Thomson was entrusted the details of the work.

In entering the investigation the Institute established the broadest kind of foundation, says the Boston Transcript. It took up the matter of comparative cost and efficiency of horses, gasolene motors and electric trucks; it considered light loads and heavy ones; it observed the efficiency of all kinds of teaming, from the delivery

Digitized by Google

of parcels to heavy moving between freight terminals. It further set its students at work observing conditions that might effect teaming such as congestion in the streets, at the freight terminals, and here a great deal of new and important work has been done. It has further laid out for the future, when other funds may be available, the effects on business of the different kinds of pavement and the relations of these to the different kinds of vehicles.

The fundamental question to be discussed is as to the advantages or disadvantages of electric trucks for real commercial work. This is a field in which there is very little information as to costs, and the company, despite its own facilities for making tests, turns to the Institute, which has the plant and the working force, and whose findings shall have an authority beyond question. The whole matter has been taken up as a plain business problem, and the present question lies in the service performed in the transportation of merchandise within a thickly populated area—city and suburb—under actual conditions. It has been necessary to analyze the service, note the relationships between each element and the cost of operation, and repeat the analysis for each different kind of trucking and for the three kinds of vehicles. Thus far the Technology study has been along two lines—the determination of the demand of the different kinds of service, and, second, the study of the relative economy of the three types of wagons when used in any given service.

The method employed to get at the facts was first to secure a continuous record of the work of each kind of truck. This was done by means of recording devices. It is possible with these, knowing what the stops are, to determine the time of movement between such places, the rate of speed everywhere and the time of standing still. Each day's work is thus recorded, and the collation and comparison of many such records gives the possibility of determining efficiency. The little clocks have been placed on the wagons of a dozen firms and about seventy records are received each day. The vehicles that are thus gathering information for Technology are engaged in their regular work with their regular employes. They present selected types of city work—pick-up, furniture moving, freight handling, wholesale and retail coal delivery, parcel delivery, market delivery and the different services of an electric company and miscellaneous hauling. The vehicles vary in size from one-horse to three-horse wagons and in the motor vehicles from 700 pounds to five tons.

There are certain hitherto obscure and, indeed, unconsidered factors to cost that the work of the past year has been clearing up, the cost to teamsters of congested streets—very important in Boston—of insufficient railway platforms and the like. A truck can do in a working day only the number of miles it can go plus the time taken for loading, unloading and standing. The latter are factors not hitherto much considered. They are more important when motor trucks are in question. For example, a horse-drawn truck with a two-ton load can be counted on in city streets for a maximum of 15 miles a day, while an electric truck in the same service is good for about 35 miles. With the speeds that are practicable, three and one-half miles an hour for the horses and six and one-half for the motor, the horses will make their mileage in four hours a day, while the motors must keep moving five and one-half hours. There is little gain in a nine-hour day in reducing the standing time of the horses to less than 55 per cent. of the whole time, while the electric truck must not stand longer than 45 per cent. of the time. It is possible, therefore, to name conditions under which horse-drawn vehicles may be more economical. It is perfectly true that mechanically driven wagons have great advantages in rapidity of movement and radius of action over the horse, but it must not be forgotten that cost proportions in a business are very important. If the cost of hauling merchandise of a given class should be very small in proportion to other costs, the matter of a few cents a ton for haulage may really be secondary to such points as reliability and punctuality.

The moral of this part of the investigation is that what is eminently successful for one kind of business may not be economical for some other business. It is necessary for the merchant to put his choice of kind of vehicle on the requirements of his business. Every class of service must be considered by itself.

One matter that has been determined as fundamental, is that for parcel delivery, nine hour day, three trips, four parcels delivered per mile and one minute consumed in each delivery, three-quarters of an hour being allowed for loading and unloading and the maximum load being half a ton, the horse-drawn wagon does only two-thirds as much work a day as either the electric or the gasolene truck, at a cost per delivery of 5.9 cents (horse), 5.4 cents (electric) and 6.5 cents (gasolene), respectively. The cost per mile by horse is likewise between the other two costs. In the delivery of coal, which is moved in large lots and to a single place, with loads of five tons, the horse wagon (three horses, one resting every third day) does only about half as much work as either of the motor trucks. The cost per mile runs in the way as with the lighter delivery, viz., 55 cents, 47 cents and 58 cents, while the cost per delivery is $3.91 with horses, against $3.32 and $4.07.

But if some special service requirement is introduced, for example, a parcel delivery requiring two minutes per call instead of one, there is an increase in the standing time, a reduction of the mileage per day, while the cost of delivery is raised. The amount of this raise will be surprising to everyone, for it seems almost a negligible matter, but the fact is that with the electric vehicle the increase is 27 per cent. against 30 per cent. with the gasolene truck and 22 per cent. with the horse-drawn wagon.

Such facts as these show the importance of the investigation, for the real relations between the delivery and the other costs have not hitherto been known. Another outcome, one that is most important to the business man is the evidence of lack of uniformity in accounts. Much stress may naturally be laid on operating expenses, and yet the estimates may omit essential features. It was found, for example, in one case that the driver's wages were not included in the teaming costs; it is quite customary to make no charge for garage. Insurance and taxes are usually omitted, while depreciation, administration and interest, very essential factors, are sometimes not included.

Some of the details that have been worked out by the students of the institute for thesis work in connection with this investigation are interesting. One of the theses presented at Commencement had reference to the investigation of the traffic conditions in the Fitchburg division freight yard. It was a study to determine whether conditions are favorable. There is time consumed in entering the yard, backing, unloading or unloading and waiting. The investigation was carried on under all kinds of weather and business conditions, and pointed out as one item that the delays within the freight yard amount to only one per cent. of the whole trucking time. Such a showing is indicative of excellent administration of the yard, and it may be said that other parties, one of which was in each yard, find in general the same condition. The investigation according to the young man who read the thesis, Herbert Louis Woehling, of East Orange, N. J., shows that motor trucks are time-savers in congested places like freight yards and he suggests the ultimate supremacy of them over the horse for such work.

One of the items in this research was the time required for backing, a process very necessary in freight yard work. It was found that a one-horse wagon requires one and one-half times as long to back as the motor truck, the two-horse wagon twice as long and the four-horse hitch two and one-third times as long. In addition, the horses occupy valuable space and the motors can squirm better through a congested passage. There are students now following the wagons seeking the causes of certain delays. The work is to determine the reason, which may be, for example, waiting at a freight house for a door.

Squeaks that Arise from Speedometers.

One point which requires lubrication, but which is oftentimes neglected, is the interior of the flexible speedometer driving shaft, to which an elusive squeak often can be traced. The best lubricant for the shaft is a light grade of grease or non-fluid oil.

WORM GEARING AS IT SHOULD BE AND AS IT IS

Terminology Criticized and Alternatives Suggested—Arguments For and Against the New Silent Driving System—Qualities That Make for Efficiency, and Details of Special Testing Appliances That Indicate the Degree of Efficiency.

Due undoubtedly to the material advances that have been made of late years in the production of mechanical parts of extreme accuracy, the worm drive has been brought to a stage of development where it is giving satisfaction in actual service not only in pleasure cars but in commercial vehicles of the heavy type, and as a consequence, interest in this silent, smooth and, under proper conditions, efficient drive is growing—not, perhaps, with the proverbial leaps and bounds, but at a healthy rate. It probably will be heightened by the paper, "Worm and Helical Gears as Applied to Rear Axles," read at the summer meeting of the Society of Automobile Engineers by Frank Burgess, the general manager of the Boston Gear Works, of Boston, Mass., in which it is stated that mileage records of from 50,000 miles to 124,000 miles have been attained with worm gear drives, and in which the author of the paper expresses his belief that in the near future a large percentage of the cars in the United States will be worm driven.

Burgess calls attention to the variety of terms applied to this drive, such as worm gear, helical gear and spiral gear, and points out the error in the use of the term "spiral," which, properly speaking, means "a line generated by progressive rotation of a point around a fixed axis with constantly increasing distance from the axis." This form is well illustrated by the hair-spring of a watch, which is a spiral and obviously differs entirely from the form of the gear in question.

"I suggest standardization of terms," says Burgess, "and that to avoid confusion any gears of the helical type transmitting motion with shaft angle at 90 degrees with a speed reduction of less than 10-1, be termed 'right angle helicals'; and with any other than 90 degree shaft angle the term 'helicals,' stating specifically the exact angle of shafts. If shafts are paralled the term 'helical spurs' should be used.

"As the term 'right angle helical' is not as convenient as the term 'worm gear', and inasmuch as for automobile work most ratios will be less than 10-1, with 90 degree shaft angle, I would suggest the term 'helical gear' as most appropriate. Otherwise it would be better to use the general term 'worm' or 'worm gear' to include all reduction ratios, even as low as 1-1. This matter should be settled promptly one way or the other."

After calling attention to the fact that worm gears, like most so-called new things, are really extremely old, the question of the relative merits and demerits of the worm gear are thus taken up:

"The principal reason for the adoption of

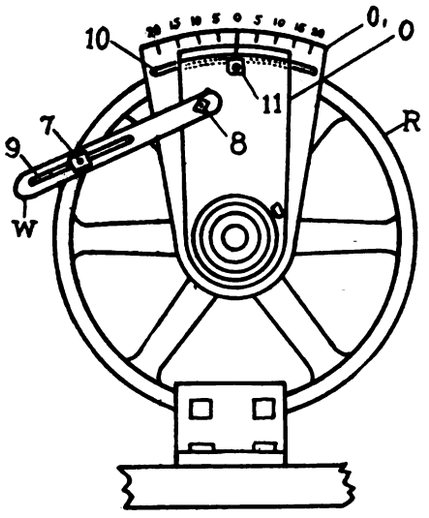

FIG. 1

the helical form of tooth appears to be its peculiar quality of silence, regardless of speed or load. With the best methods of de-

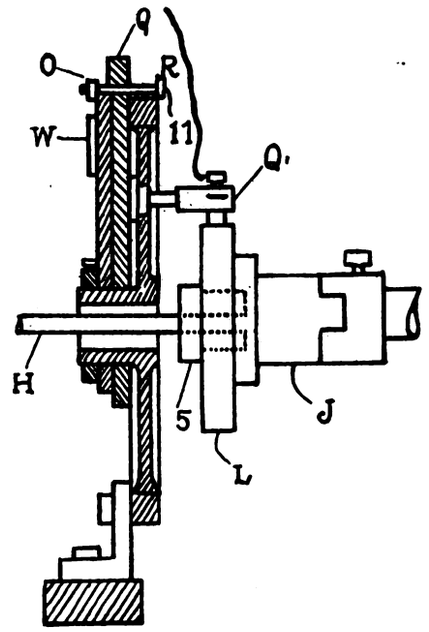

FIG. 2

sign and assembly, great durability, strength and efficiency are obtained. It is impracticable in an article of this character to cover all the details satisfactorily. However, I believe that on all styles of cars in the United States to-day the worm gear could be used successfully for rear axle purposes.

"The successful worm gear should embody the following qualifications: 1. Cheapness of construction. 2. Strength for resisting shocks. 3. Hardened and smooth surfaces for durability. 4. Material of a suitable composition to reduce friction. 5. Simplicity of construction and mounting. 6. Perfect bearing condition. 7. Noiselessness at any speed or load. 8. Reversibility. 9. Lightness in weight. 10. Efficiency in power transmission.

"Granting that there is some argument against the worm in regard to trucks as to the dead axle proposition, this could be overcome by using the worm gear on each end of the axle, the same as sprocket wheels, having a double worm gear drive in place of the cumbersome chain drive. If at first slightly more expensive than the chain and sprocket drive, less repairs will more than make up the difference. Care should be taken to have accurate and first-class bearings, both radial and end-thrust.

"Considerable discussion has arisen in regard to the relative merit of the straight and Hindley types, the latter having been first used by Hindley, of York, England. In my opinion both can be used successfully, although each has its own advantages and disadvantages. For most purposes, particularly where considerable power is to be transmitted, the Hindley has the advantage, but with ordinary machinery it is somewhat more difficult to obtain the same degree of accuracy that can be obtained in the case of the straight type.

"From tests made there is no question but that there is a larger bearing surface on the Hindley type of worm than on the straight. Therefore this type of gearing will for the same pitch present a bearing of greater durability and manifestly heat less than the straight type, particularly under heavy load.

"The straight type may have less trouble with end-thrust bearings. The worm can move in its position longitudinally with the worm axis and therefore does not require as close adjustment of the end-thrust bearings.

"With first-class bearings the Hindley type has the advantage, as a smaller and lighter gear can be used, thus reducing expense, especially if made up in large quantities.

"The worm gear should be made of a

Digitized by Google

special mixture of hard bronze. The gear should be slightly polished after being cut to insure a perfectly smooth glazed surface to mesh with the hardened polished worm. This set of gears, properly housed, with ball bearings and the right lubricant used, will give an efficiency of at least 90 to 95 per cent.

"A simple method of testing the gears for efficiency without elaborate apparatus is to run them in their regular housing, containing a bath of oil, subjected to load to be transmitted. If they do not have a high temperature after running several hours they indicate high efficiency and suitability for the given purpose.

"That there may be a satisfactory method of knowing whether gears will be suitable before being placed in cars and tested on the road, insuring proper efficiency and absence of excessive heat finally destroying their usefulness, it is quite necessary that manufacturers of rear axle drives using this form of gearing should have a proper way of testing exactly the efficiency of the gears. It would be very expensive to replace the gears after installation. After a careful study of the best mechanical and electrical absorption and transmission dynamometers, an efficiency testing machine, similar in some respects to the apparatus used at the Massachusetts Institute of Technology by Prof. F. C. Riley, was constructed during 1911. The prony brake was adopted for an absorption dynamometer and a long shaft of a small diameter arranged to obtain the torsion of the shaft in degrees by an electrical indicator apparatus for a transmission dynamometer. This efficiency testing apparatus is shown in Figs. 1, 2, 3 and 4. On shaft H is worm 1 driving the worm wheel 2 on shaft 3, on which are prony brake wheel Y and brake-arm Z bearing on platform scales X. On each end of the shaft H are clutches I and J, in which are fitted bushings 4 and 5, in which the shaft H is sweated. Attached to clutches I and J are fiber discs K and L in which are inserted brass contact-points making electrical connection through the fiber discs to shaft H. Bearing on the peripheries of these fiber discs are spring-brushes Q and Q_1, to which are fastened insulated copper wires, in the circuit of which are located dry batteries U and the telephone receiver T. Spring-brush Q is fixed while spring-brush Q_1 is attached to sector O_1 concentric with the shaft H movable on lug of fixed iron wheel. Sector O is graduated each side of zero to 20 degrees in ½ degrees. Sector O_1 is fastened to fixed wheel R by link W and bolts 7 and 8 and is adjustable a small amount by slot 9 through which bolt 7 is clamped to wheel R. This sector O has a zero marked at the top, which moves over the graduated sector O_1, thus enabling a fine adjustment of the zero point so that the spring-brushes Q and Q_1 may be brought to coincide at the same angle. Sector O_1 is clamped to fixed wheel R by a bolt 11 through slot 10, which enables readings from zero to sector O to be determined. As the load is applied to the brake, the shaft of fiber disk L begins to lag behind the fiber disk K and the amount in degrees which this shaft lags is recorded by sectors O and O_1. The horsepower transmitted can be determined per degree

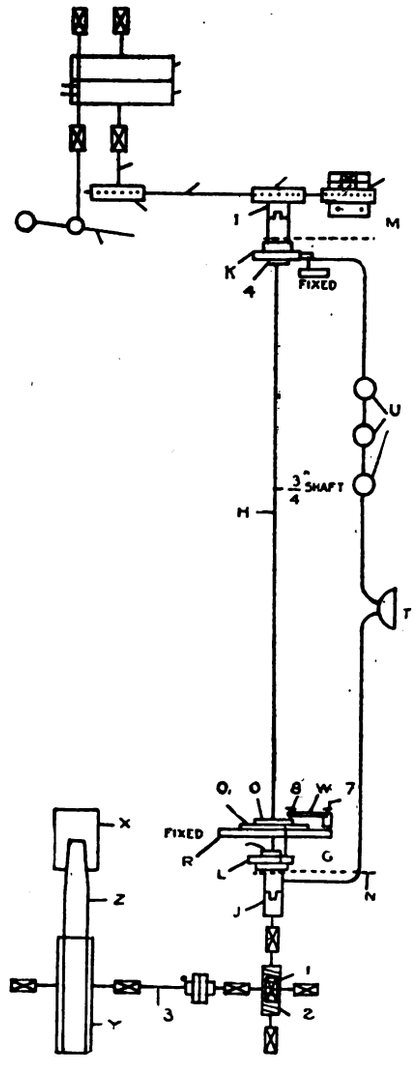

FIG. 3

or ½ degree by previously calibrating the shaft by means of levers N and M clamped to clutches I and J temporarily, M being fixed.

"The power supplied or the in-put being

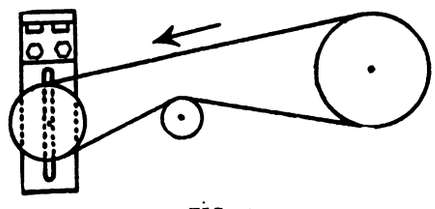

FIG. 4

found and the power absorbed obtained, the efficiency of the worm and worm gear and bearings can be found by dividing the out-put by the in-put. This apparatus appears to be accurate and the simplest and cheapest method of determining the efficiency of worm gears that I have thus far been able to find."

Radical Features of a French Car.

Of the 51 racing machines which were entered in the French Grand Prix race, none were more interesting from a mechanical standpoint than the three Sizaire-Naudin cars .The four cylinders, measuring 78 mm. by 56 mm. bore and stroke, respectively, are cast separately without end walls for the jackets, and on being mounted on the crank chamber are bolted together by a series of longitudinal bolts passing from end to end of the series, and by lugs and short bolts at the top and bottom of each cylinder. This construction not only provides the advantage of separate casting permitting careful verification of the cylinder wall dimensions, but also provides all the advantages of the block casting, since, when bolted together, the cylinders are as rigid as if they were cast in a single piece.

Four valves, two each exhaust and inlet and all 2⅛ inches in diameter, are provided for each cylinder, while but a single ring prevents the flow of the gases past the light steel piston rings. Three spark plugs, two of which are sparked by means of a dual magneto and the third by a single spark Bosch magneto, are positioned in the head of each cylinder and render the ignition certain. Probably more unusual than any of the other details, however, are the constructional details of both front and rear axles. In reality there is no front axle, its place being taken by a single cross spring. No differential is provided on the rear axle which is a solid steel shaft fitted with a single bevel pinion. The pinions of the gear set, which is housed in a casing integral with the rear axle casing, engage with the bevel gear on the solid axle. Four speeds, and each of them providing direct drive, are embraced in the gearset design.

Ohioans Take up Warehouse Trucks.

The Cleveland-Galion Motor Truck Co., of Cleveland, O., which is the title of the recent amalgamation of the two concerns of those names, has departed radically from the previous productions of the separate companies. Instead of gasolene trucks, the Cleveland-Galion company is featuring an electric platform truck, styled the Dynamic warehouse truck. In general design, it follows other contrivances of the sort and resembles a railroad baggage truck; it is equipped with electric power, controlled, as is the steering gear, from a small platform in front, close to the ground. Either front or rear wheels, or all four, can be used for steering.

Defloculated graphite is made by treating graphite with tannic acid. The result is that the graphite becomes so finely divided that it will pass through a filter without being deposited and will remain suspended in water indefinitely.

MENKER THE STAR AT NARBETH MEET

Kline Pilot Takes Three Events, Including Feature Race, After Blockson Blows Out—Spill Causes Excitement.

John Menker loomed large at the race-meet sponsored by the Belmont Motor Club which occurred on Saturday last, June 29th, on the Belmont Park track at Narbeth, Pa. Of six events, Menker, who piloted a Kline, won three, including the star number—a 50-mile free-for-all.

Most of the excitement of the day was contained in this particular event, which really was run twice. On the first attempt there were four starters—Menken, W. D. Morton in a Mercer, William Freitag in a Fiat, and S. R. Blockson in a Stutz. Blockson was leading at the 18th mile, which he completed in 17:57, when a tire blew out on Morton's Mercer, causing the car to skid through the fence and spill both driver and mechanician. The accident, of course, created great excitement and caused such a rush of spectators to the scene of the mishap that it was deemed the better part of wisdom to stop the race. Neither Morton nor his helper were seriously injured, but their car was hors de combat when the race was restarted. Meanwhile, Freitag's Fiat had contracted motor trouble, and he also was forced to stand down. Blockson and Menker, therefore, were the only starters. The former bore out the promise he displayed in the first attempt and led until the 49th mile, when he suffered a tire blowout which permitted the Kline pilot to win a hollow victory in 53:39. Menker, however, won on his merits in the 10-miles 301-450 class, when he defeated Blockson and Albert Millichap (G. J. G.) in 5:59. Menker's third triumph was scored in the one-mile time trials; he completed the distance in 58 seconds.

The handicap event, 10 miles, went to Freitag, who, giving away starts up to 60 seconds, started from scratch and won without greatly extending himself in 11:20. The remaining events, five miles, 161-230 class, and five miles, 231-300 class, were gathered in, respectively, by Edward Bauer (Buick) and E. Homan (Bergdoll). The summary:

Fifty miles, free-for-all—Won by John Menker (Kline); second, S. R. Blockson (Stutz). Time, 53:39.

Five miles, Class C, for cars with 161-230 inches displacement—Won by Edward Bauer (Buick); second, H. Baker (Carter); third, R. S. Smith, Jr. (Empire). Time, 6:02.

Five miles, Class C, for cars with 301-450 300 inches displacement—Won by E. Homan (Bergdoll); second, W. D. Morton (Mercer); third, Harvey Ringler (Mercer). Time, 6:00⅘.

Ten miles, Class C, for cars with 301-450 inches displacement—Won by John Menker (Kline); second, S. R. Blockson (Stutz); third, A. Millichap (G. J. G.). Time, 9:55.

Ten miles, free-for-all handicap—Won by William Freitag (Fiat), scratch; second, R. S. Smith (Empire), 55 seconds handicap; third, James Gray (Schacht), 60 seconds handicap. Time, 11:20.

One mile, time trials—John Menker (Kline), time, 0:58; William Freitag (Fiat), time, 1:01; William Haupt (Chadwick), time, 1:02.

Dealers Punished for "Stock Car" Ads.

For advertising the victory of Joe Dawson's National car in the 500-mile race on the Indianapolis Speedway as the performance of a stock car, the Wisconsin Auto Sales Co., of Milwaukee, and the Howard Automobile Co., of San Francisco, who are National agents in their respective cities, have been disqualified and suspended until January 1st next by the contest board of the A. A. A.; and for similarly advertising the performance of a Stutz car in the 50-mile race at Salem, N. H., on June 8th, the Empire Motor Car Agency of Boston, Mass., Stutz agents in that city, has been disqualified for a similar period. The action of the contest board was taken under a rule which prohibits the advertising of the performance of a car in a sanctioned event as being the performance of a stock car, unless such events are open only to registered stock cars. The races in question were not so restricted, being Class E, special non-stock events.

A. A. A. Accepts Slower Times as Records.

In line with, but emphasizing the ridiculousness of, its rule which denies intermediate records to any competitor who fails to finish a race, the A. A. A. contest board has eliminated Ralph De Palma and his figures from the table of records set up during the 500-mile race on the Indianapolis Speedway on May 30th last and, inconsistently, has accepted as records the slower times made by men who trailed De Palma for 497 of the 500 miles, Joe Dawson's time for the total distance being the only record which otherwise would not stand to the credit of De Palma. The records booked by the A. A. A. as "official speedway records regardless of class" are as follows:

100 miles	Fiat	Tetzlaff	1:13:37.25
150 miles	Fiat	Tetzlaff	1:49:52.84
200 miles	Fiat	Tetzlaff	2:25:59.52
250 miles	Fiat	Tetzlaff	3:07:13.94
300 miles	National	Dawson	3:48:49.30
350 miles	National	Dawson	4:25:15.27
400 miles	National	Dawson	5:04:14.23
450 miles	National	Dawson	5:44:04.54
500 miles	National	Dawson	6:21:06.03

"Automobile Suicide" Becomes a Reality.

What probably constitutes a record for originality in the application of the motor car to unusual uses was created when Mathias M. Chew, a well known resident of Cecil, N. J., committed suicide one day last week by inhaling gas from the acetylene tank on his car. He was found lying beside the car near his home, with the end of the gas tube held between his teeth.

"ATHLETES" WIN FOURTH VICTORY

Defeat Chicago Automobile Club in Fifth Annual Team Contest—Heavy Penalties for Two Men the Cause.

Following the usual order of things—that is, the order which has been followed in all save one of the five annual interclub reliability tours which have been contested to date by the Chicago Automobile Club and the Chicago Athletic Association, the Cherry Circle team again defeated the Chicago Automobile Club's drivers in the fifth annual event, which was contested on Thursday and Friday last, June 27th and 28th. The total debits of the two teams, which stood at 51 and 53.165 respectively, are more nearly equal than was the case in the 1911 contest, also the penalizations of neither team is so large as last year, due largely to the good condition of the roads encountered during the 240-mile run to Milwaukee and back, and to the ideal weather which prevailed the two days.

The members of the Automobile Club team, 11 in number as against 12 who piloted the cars entered by the Athletic Club members, notwithstanding the fact that they came off second best, really made a very fine showing, for all of the penalties were recorded against but two members. the other nine completing the 240-mile run with clean slates.

The demerits which were tallied against the Athletic team were due to Grower, Gunther, Simpson and Thorne, who stalled motors and were penalized a point each; Wentworth, who had motor trouble and tallied 4 points, and Weatherly, who landed in a ditch and was penalized 43 points. On the C. A. C. team Bosch, who had motor trouble, lost 25 points, and Franklin, who was late at controls, lost 33.

The detailed score is as follows:

Chicago Athletic Association.

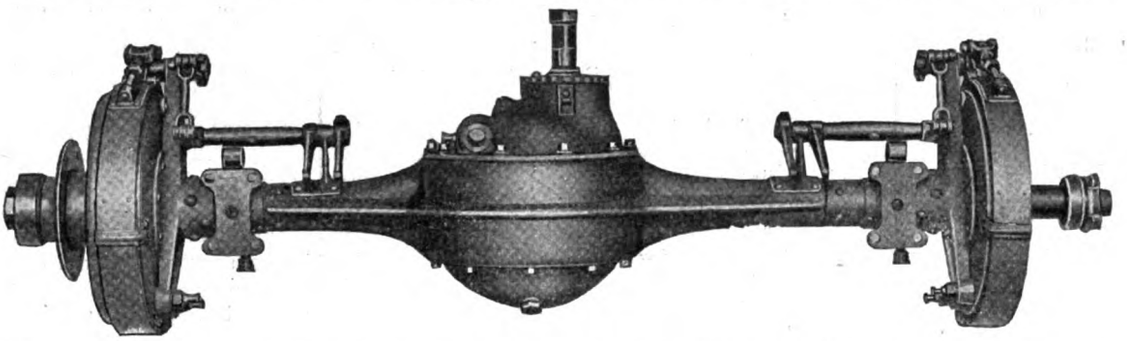
	1st Day.	2nd Day.
C. F. Knisely, Diamond T.....	0	0
Frank Wentworth, Rambler...	0	4
W. C. Grower, Diamond T....	1	0
W. C. Thorne, American.....	0	1
A. H. Gunther, Cadillac.....	1	0
W. Chamberlain, Rambler.....	0	0
C. A. Griggs, Chalmers.....	0	0
S. F. Weatherly, Pathfinder...	0	43
Harold Boulter, Locomobile...	0	0
W. Simpson, Winton.....	0	1
L. Jacques, Peerless.....	0	0
S. E. Hibben, Packard.....	0	0

Total, 51 points.

Chicago Automobile Club.

Allan S. Ray, Stearns.....	0	0
G. F. Ballou, Apperson.....	0	0
Charles Bosch, Stearns.....	25	0
J. T. Brown, Velie.....	0	0
R. O. Evans, Apperson.....	0	0
H. A. Ford, Premier.....	0	0
E. T. Franklin, Abbott-Detroit	33	0
G. F. Griffin, Peerless.....	0	0
W. M. Jones, Winton.....	0	0
F. E. Mann, Locomobile.....	0	0
R. B. Wilson, Knox.....	0	0

Total, 58 points.



Fractional penalization, 53.165.

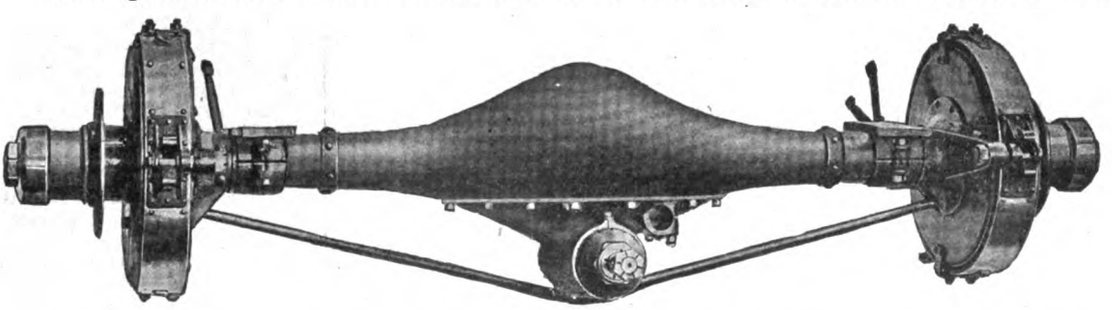
American American

American Axles

Have Universal Application to Either Gas or Electric Cars Using Bevel or Worm Gears



Whatever the type of pleasure car or truck to be equipped, there is an *American* axle for it that demands your consideration because of its sheer merit.

You now have the option of the two types of gear that have won first place in this country and England respectively.

The addition of the Lanchester Worm Gear to the *American* line of bevel gear axles instantly made *American* the synonym for axles of the highest quality for all classes of cars.

For any car weighing up to 4,500 pounds, and up to 60 H. P., there is an *American* axle of superb design, thoroughly tested model and finest workmanship, with either bevel or worm gear.

Through the Warner Gear Co., of Muncie, Ind., we hold the exclusive American rights as axle manufacturers to the use of the Lanchester Worm Drive.

THE AMERICAN BALL-BEARING CO.

Edgewater Park and L. S. & M. S. Ry. CLEVELAND, OHIO

1,010,754. Internal Combustion Engine. Allen E. Hall, Philadelphia, Pa. Filed Mar. 14, 1911. Serial No. 614,298.

1. In an internal combustion engine, the combination with a cylinder, of a piston in the cylinder, an exhaust valve in the head of the cylinder having a tubular stem, a source of cooling agent supply, a hollow rod telescoping in the tubular stem of the exhaust valve and connecting the exhaust valve and the piston, said rod communicating at one end with the cooling agent source of supply, substantially as described.

1,010,798. Internal Combustion Engine. Adolph Potdevin, Brooklyn, N. Y., assignor to Potdevin Machine Company, Brooklyn, N. Y., a Corporation of New York. Filed Jan. 4, 1911. Serial No. 600,699.

1. In an internal combustion engine of the two-cycle type, the combination with a piston, of a cylinder therefor having an explosion chamber and an exhaust chamber, the former chamber having therein primary and secondary exhaust ports and a gas inlet port, the secondary port communicating with the exhaust chamber and the several ports being of progressively increasing areas, whereby the piston itself in its outer or power stroke first partially opens the primary exhaust port, then the gas inlet port, and then the secondary exhaust port, all the said ports being fully open when the piston reaches the limit of its said stroke.

1,010,803. Detachable Wheel. Victor Riley, Hollybank, Coventry, England. Filed Sept. 7, 1911. Serial No. 648,194.

The combination with a detachable hub carrying a nut free to turn in it and provided with a pawl adapted to engage with a ring of teeth in it; of a cover pivoted to the nut and adapted to be turned over the pawl and to hold it in engagement with the teeth and means for controlling the movement of the cover in such manner that when it is not above the pawl it projects beyond the periphery of the nut.

1,010,806. Indicating Tail Lamp. Maurice S. Rosenfeld, New York, N. Y., assignor to The Warning Signal Lamp Company, New York, N. Y., a Corporation of Maine. Filed Aug. 26, 1910. Serial No. 579,166.

1. An indicating tail lamp comprising: a frame, and means adapted to secure the same to the vehicle; a horizontal base secured to said frame, and suitable lamps carried by the same at the opposite ends thereof; a box to receive light therefrom and resting upon said base, and mechanism within said box to display a suitable warning; and detachable chimneys for each of said lamps adapted to secure the said box to the said frame.

1,010,883. Wheel Brake. Samuel D. Forman, Tonopah, Nev. Filed Mar. 12, 1910. Serial No. 548,930.

In combination a wheel hub, a sleeve rotatably mounted on the hub, spokes radiating from the sleeve, a wheel guard mounted on the terminals of the spokes, an arm connected with the sleeve, a link connected with the arm, a lever pivotally supported and pivoted to the link, stops secured on the wheel guard at radially spaced points, and arms adapted to engage the stops to limit the movement of the wheel guard on the hub in either direction.

1,010,884. Cross Chain for Anti-Skid Devices. Floyd Henry Fox, New York, N. Y. Filed July 18, 1910. Serial No. 572,563.

1. A link for a cross-chain of an anti-skid device for tires comprising a body portion having a circular opening formed therein and a bearing stud secured in said opening, the side edges of the body portion being inturned and bearing against opposite sides of the bearing stud.

1,010,885. Anti-Skid Chain. Floyd Henry Fox, New York, N. Y. Filed Aug. 20, 1910. Serial No. 578,147.

1. A cross chain of an anti-skid device for tires, having therein a link comprising a body portion having an opening therein and side wings bent upward and inward, and a bearing stud comprising a head having its sides bearing against the side wings and having at its lower end a projection extending into and secured in the opening in the body portion of the link, the end of said projection being flush with the lower face of the central portion of the link, the bearing stud also having a shoulder formed in its head and a tongue on the body portion of the link curved downward below the plane of the central portion of the link and then upward and inward to form a loop, with its end resting on the shoulder formed on the head of the bearing stud.

1,010,904. Carburetter. William Andrew Harris, Greenville, S. C. Filed Feb. 3, 1911. Serial No. 606,299.

1. In a device of the character specified, a receiver, means for supplying air to the receiver, said means comprising a casing, a movable bell for the casing, a water seal between the bell and the casing, a cylinder arranged concentric within the casing, a piston in the cylinder, a rod connecting the piston with the bell, and means for alternately admitting water to the cylinder and discharging it therefrom to raise and lower the bell, said means comprising a valve casing having at one end a passage for connection with a water supply and having at the other end a connection with the cylinder, the valve casing having a discharge opening, a valve in the casing having means for connecting the first-named passage with the second-named passage, or with the discharge opening, a disk journaled on the valve, a roller extending laterally from the disk near each side thereof, a vertically movable rod having a finger for engaging the roller to oscillate the disk, a counterbalance connected with the disk for completing the movement thereof, a connection between the disk and the valve for moving the same, stops for limiting the movement of the disk, a sleeve on the bell of the casing through which the rod is slidable, a stop adjustable on the rod on each side of the sleeve, a pump for supplying gasolene to the receiver, means on the bell of the casing for operating the said pump, means for controlling the supply of water to the valve, and means controlled by the volume of the contents of the receiver for actuating the said water controlling means.

1,010,935. Clutch. Mark D. Meek, Eau Claire, Wis. Filed Sept. 22, 1910. Serial No. 583,255.

1. A clutch comprising a driving element, an interiorly grooved ring carried at one end of the element, a hollow shaft, keyed to ing the element, a driven element, keyed to the shaft, a plurality of outwardly flaring V-brackets arranged circularly against the inner side of the driven element and projecting into the ring, pairs of links hinged between the V-brackets, shoes hinged upon the links midway of their ends, friction blocks carried in the shoes and seating in the groove of the ring, a collar loose upon the shaft within the ring, a band rotatable in the collar, arms connecting the outer ends of the links to the band, and a movable rod arranged in the shaft and having connection with the collar for moving the same.

1,010,965. Headlight for Vehicles. Anton Seuss, Pittsburgh, Pa. Filed Apr. 21, 1911. Serial No. 622,560.

In a lamp shifting mechanism for automobiles, brackets positioned upon the inner sides of the frame of the vehicle and each consisting of inwardly projecting arms provided with vertically alining perforations, a boss upon the outer face of the upper of said arms and provided with a ball race, a pin revolubly supported by said arms and extending through said perforations, a head upon said pin, said head provided with a ball race opposing the ball race in the boss carried by the upper of said arms, antifriction members interposed between the head and the boss in said races, lamp supporting arms carried by the said head, and means for shifting in unison the pins carried by the arms of said brackets.

1,010,968. Vehicle Top Fastener. William Spickernagle, Owensboro, Ky. Filed Feb. 6, 1911. Serial No. 606,869.

1. A canopy fastener comprising a supporting frame provided with pendent lugs, said lugs being provided with oppositely disposed transverse grooves, latch casings carried by a vehicle seat, latching bolts in said casings having end slots for interlocking engagement with the grooves of said lugs, supporting tubes for said casings, rods extending through said tubes and having crank arms for operating said bolts, springs coiled about said rods and opposing rotating of the same in one direction, connecting rods, links connecting the last-mentioned rods to the bolt operating rods, crank arms carried by the connecting rods, a hand lever, and link connections between said hand lever and the last-mentioned crank arms.

1,010,974. Ball Retainer. Jackson L. Straub, Lancaster, Pa., assignor to The Star Ball Retainer Co., Lancaster, Pa., a Corporation of New Jersey. Filed Oct. 7, 1910. Serial No. 585,889.

1. A ball retainer and separator for ball bearings consisting of a base-ring with spaced standards rising from one of its edges, the free ends of the standards overhanging said base, the latter being corrugated, thereby providing ball-seating depressions between the standards, said depressions extending transversely of the axis of the ring and having the effect of increasing the length of the standards and lessening the distance therebetween.

1,010,980. Vehicle Tire. Ellsworth Tallman, Morley, Iowa. Filed Apr. 28, 1911. Serial No. 623,855.

1. A vehicle tire, having a rim provided with a plurality of hinge pin sections; a plurality of juxtaposed U-shaped metal spring members, said members being provided with hook-shaped ends adapted to engage said hinge pin sections; and a plurailty of latches for locking said hinge pin sections within said hook shaped ends.

1,010,987. Make-and-Break Sparker for Internal-Combustion Engines. Elihu Thomson, Swampscott, Mass., assignor to General Electric Company, a Corporation of New York. Filed Aug. 17, 1907. Serial No. 388,979.

Digitized by Google

1. The combination with the cylinder of an internal combustion engine, of a removable spark-plug comprising a movable insulated abutment, sparking contacts controlled thereby, and means for imparting impulses to said abutment from a source outside of said cylinder.

1,011,013. Vehicle Tire. Asplan Beldam, Baldock, England. Filed Sept. 14, 1911. Serial No. 649,337.

1. In combination, a wheel, spaced apart blocks formed with openings, and mounted on the rim of the wheel, springs mounted in the openings and extending beyond the outer plane of the blocks, a tire supporting rim mounted on the springs, a tire secured to the tire supporting rim, abutments extending inwardly from the tire supporting rim, abutments extending from the rim of the wheel, projections extending from two adjacent abutments on the wheel rim and engaging the opposite side of one of the abutments on the tire supporting rim, springs between the abutments on the tire supporting rim, and the abutments on the wheel rim to provide cushions, and side plates extending from the rim of the wheel to the tire supporting rim to inclose the springs.

1,011,051. Speedometer. Louis A. Greenleaf, Dorchester, Mass. Filed June 9, 1910. Serial No. 566,034.

1. A speedometer comprising an inclosure, a continuous hollow cylindrical member therein, means for holding said member in spaced apart relation to the walls thereof to leave an open annular space, air current producing means wholly within said cylindrical member, a driving connection thereto, and means also wholly within said cylindrical member responsive to an air current and having connected thereto a device to indicate the force thereof, said parts being constructed and arranged to produce a closed circulation of air in the direction through the interior of said cylindrical member, returning in the opposite direction through said unobstructed open annular space.

THE
MOTOR WORLD

"The paper that's read, not merely looked at"

furnishes the strongest dollar-for-dollar advertising value ever offered to the manufacturers of

Automobiles : Parts
Appliances

Inquiries received from Motor World advertising are always worth while following up. They come from men actually engaged in the automobile trade and who have a vital interest in making the inquiry. Such inquiries are worth vastly more than those prompted by mere curiosity.

The Motor World Publishing Co.

Weed Chains

The Great Anti-Skid DEVICE

Nine-tenths of all accidents to automobiles are caused by skidding or slipping.

Either you skid into the "other fellow" or the "other fellow" skids into you.

No matter how careful a driver you may be, you cannot prevent skidding or slipping on wet, muddy snow-covered roads or on icy, slippery greasy pavements unless you equip your car with Weed Chains.

Cannot Injure Tires

Because They Creep

An absolute necessity on both rear wheels and if you want to know what real steering steadiness means put them on the front wheels too.

For your own safety—for the safety of the public, fully equip your car with Weed Chains. Make it your business to get a set today.

A trouble saver for the motorcyclists

This book contains more practical advice for the rider, more good hard sense, more suggestions as to how to keep out of trouble, and how to get out of it, than has ever been printed heretofore in any one book.

¶ It fits the coat pocket and it includes free engine clutches, two-speed gears, mechanical lubricators and magnetos, together with special matter on motors, valves, carbureters, fuel and important general subjects, all plentifully illustrated.

¶ Dealers and jobbers in all parts of the country are selling "Care and Repair of Motorcycles" to both new riders and veterans as the best aid in correcting and avoiding motorcycle trouble.

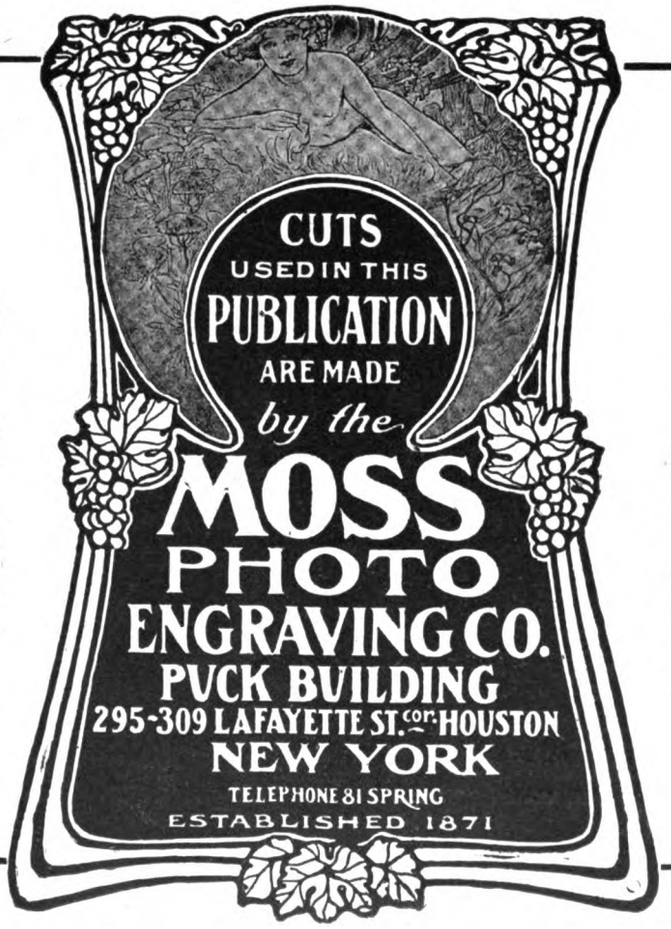
The desire to make good tires plus the ability to make good tires—makes good tires

That is all there is to the tire question.



Some other man's mileage won't make your tires last any longer. The longevity of good tires depends upon the conditions under which they are used, the way the car is handled, the kind of roads it travels and the weights that must be carried.

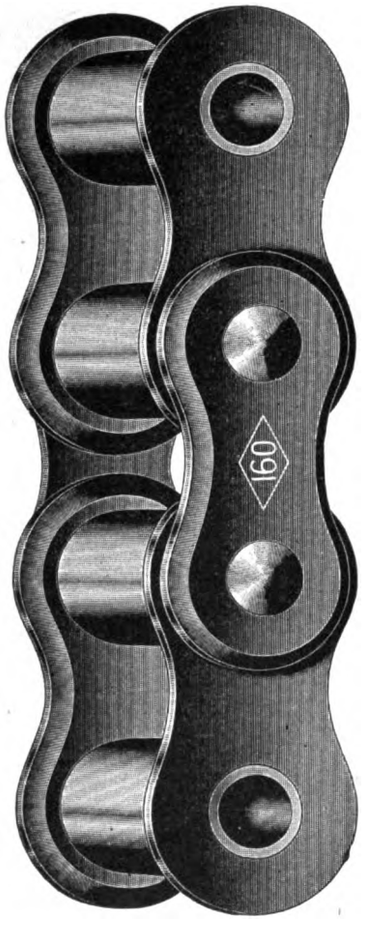
Constructive principles are pretty much the same; therefore, in selecting tires, it is well to go back to first principles and find out who wants to make good tires and who can.

This company was the first to make rubber tires to take the place of iron tires on all vehicles, and it has been making rubber tires of various kinds ever since. The Kelly-Springfield solid tire has had a longer but not a greater success than the

Kelly-Springfield
Automobile Tire

Kelly-Springfield Tire Company, 20 Vesey Street, New York

OUR REPUTATION



is based on the fact that we have been handling the engraving of several prominent trade and general publications for years to the utmost satisfaction of both publishers and advertisers

SERVICE

The quality of work turned out by this plant is re-inforced by our facilities for deliveries as promised. Your work will be put through with the same care and dispatch given to publishers whose work must be right—and "right on the dot."

Digitized by Google

A prominent automobile manufacturer says:

"We have used Diamond Chains for years. We are pioneers of solid tired vehicles and Diamond Chains have pleased our customers. I do not hesitate to tell you that they are our sole standbys."

This is what the sales manager of a large automobile manufacturer wrote an interested engineer on the above subject.

Twenty-two years of progressive development and constant supremacy in the manufacture of machined chains enable us to offer to Diamond Chain users a chain of long life and absolute reliability.

Diamond Chains must test up to a fixed high standard before leaving our factory, and this test invariably involves a duty greater than that for which the chains are designed and sold. Our engineering department will advise freely on design problems. Write for our treatise "Power Chains and Sprockets."

Mr. Automobilist:

Your tire maker is very anxious to impress upon you the importance of

Tires Inflated to the Right Pressure

He insists that this is tire economy and

Saves You Money

How do you know what pressure you have in your tires? A

SCHRADER
UNIVERSAL
Tire Pressure Gauge

(Trade Mark Registered in U. S. Patent Office)

(Patented March, 1898—Other Patents Pending)

will tell the exact pressure in your tires at any time, day or night, by simply holding this Gauge to your Valve for a second. Its recording sleeve remains in place, showing the exact pressure in the tire so that the Gauge can be taken anywhere and read, at night to the front of the car into the light of the lamps. After the pressure has been ascertained the Indicating Sleeve can be pushed back into the Gauge with your finger. No catches or snaps to operate or get out of order. This Gauge is 2½ inches long over all, short enough to apply easily to the smallest diameter of wheel and can easily be carried in the vest pocket or the change pocket of your trousers.

Price $1.00 Each

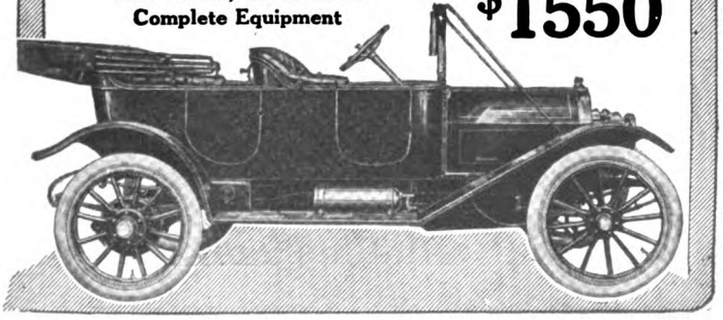
Learn From the Book—Why the Glide is Best

If you are contemplating the purchase of an automobile you can make no mistake going to a "Glide" dealer. In the first place, a "Glide" dealer has a car that he can sell with absolute confidence and with the knowledge that the automobile will give

5 to 7 Years' Service



Then again he knows that his customer becomes the purchaser of a car that combines quality and price in a way that has never been equalled by any automobile manufacturer.

If these things count for anything—and they surely do—then the "Glide" has a perfect right to call itself the *best* car—and the best car is the car you want. You can learn all about the "Glide" and the *guarantee* back of it from the handsome book we send free to all those interested. Booklet pictures and describes full line including Two and Four Passenger 45 h. p. cars, $2,000; Five Passenger "45" $2,150; Seven Passenger, "45" $2,250.

To Dealers: We intend to establish a few new selling agencies in territories which are still open. Write for our proposition. The "Glide" has made good for other dealers—it will make good for you. Write for information today.

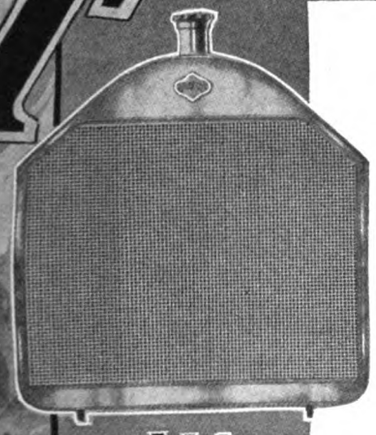
Mr. Automobile Owner: We find in the different advertising matter put out by infringing competitors, the statement that their air gauge has no **snaps** or **catches** to get out of order.

No, they haven't, but they do have **rubber washers** and **rubber bags,** which as you know, will deteriorate and harden so that in three or four months the gauge is worthless. Besides the tube is held by friction, and you know that where there is friction, there is wear.

Now the TWITCHELL does not have rubber washers or bags to deteriorate. There is no tube controlled by friction to wear, consequently giving you incorrect pressure. The TWITCHELL is positively accurate at all times and the only way that you can put it out of commission is with a **hammer.**

The Twitchell Air Gauge



tells you in a minute if your tires are properly inflated. That is why the TWITCHELL AIR GAUGE is tire insurance; that is why it is a guarantee of maximum tire efficiency.

You simply apply the gauge to your valve and the indicator shows your tire pressure. A stop holds the indicator in place till you release it. On every gauge is a table of pressures different size tires require.

Price $1.00 Each **NOW READY FOR SHIPMENT**
Can be obtained from your dealer

THE TWITCHELL GAUGE CO., 1256 Michigan Ave., Chicago

Fedders SQUARE TUBE RADIATORS

ALL FOUR SIDES SURROUNDED BY WATER

Efficiency, service and economy are the chief characteristics of Fedders square tube radiators.

All four sides of each pure copper tube surrounded by water make a Fedders square tube radiator perfectly efficient in the performance of its cooling function.

The water space between the tubes being reasonably wide, there is little or no danger of a Fedders square tube radiator ever becoming clogged up—this means perfect service. It also means economical service for Fedders square tube radiators always cool their engines; that is, if the engines are normal.

Any tinsmith can repair a damaged Fedders square tube radiator at little or no cost. Most other radiators must be shipped to the radiator factory to be repaired. More Fedders economy.

Wire us for more detailed information. While the square tube is our leader, we are in position to make almost any type radiator desired. Send us your blue prints and specifications and let us quote you.

The ONLY Starter Plug

It was almost impossible to put the simple, successful acetylene gas starter on cars without petcocks UNTIL THIS new plug was perfected.

NOW you can put a self starter of the type of the DISCO on FORDS, BUICKS, ELMORES, and all cars whether they have petcocks or not. This is the ONLY STARTER PLUG. Patents pending.

Takes the place of all other spark plugs. Gives splendid ignition results—withstands heat, is soot proof and easily accessible for cleaning and inspection.

Schafer Ball Bearings

are built to withstand the most extreme strains and stresses of hardest service.. The durable, wear-resisting chrome steel used in their construction is of exclusive analysis, free from blisters, air bubbles and every intrinsic weakness that might cause the balls to vary in weight, size or structural strength. The balls are uniform to within .0001 part of an inch and remain so over long terms of hard service. Recognized by engineers as the highest grade and finest quality of anti-friction bearings made today. When you equip with Schafer you insure your car against frictional deterioration.

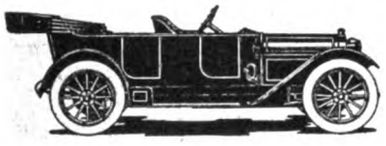
The Motor With the Sliding Crescent Valve

KNIGHT-DAVIDSON
1896 — 1912

The CRESCENT valve of the K-D Motor, fitting around the stationary piston wall affords a larger port area than any other poppet or slide valve on the market. It is simpler and, consequently, better than any other valve construction known and is here offered to discriminating manufacturers, not as an experiment, but as a tried, tested and proved mechanical advance. The K-D motor is simple, silent, cools rapidly, has the simplest oiling system known, will not carbonize. Last and most important, will give on a given quantity of fuel more power, speed and endurance, unit for unit, than any other engine on any type of an automobile. We want to present some facts to interested manufacturers.

KNIGHT-DAVIDSON COMPANY, Boston, Mass.



KNIGHT-DAVIDSON

If You Need Motor Lamps

You Need This Catalog

We want you to write for the Solar Catalog before you decide on your motor lamps, for this is the most complete line of lamps on the market. Solar Lamps have been preferred by most motorists for the past fourteen years because of their brilliancy, their style, their strength and their several exclusive advantages—their special short focus lead glass lens mirror reflectors—the patented double ray light projection (in the Solarclipse), giving two distinct fields of light, for city and country use—the new black finish, the only such finish that's proof against heat and moisture—and other features that other lamps lack.

To fail to see Solars before you buy is to fail to include in your consideration the very finest lamps in existence. Solars are made for oil, electricity, gas and in combination, for pleasure cars, motor trucks, carriages, motor boats and airships. Write for catalog now—while you think of it. (136)

YOU CAN STILL WIN THAT $100

by naming this new signal

In thinking of your suggestions for a name take these facts into consideration:

The motor-driven signal has long been recognized as the logical—the most practical—the *ultimate* type. Its sole draw-back has heretofore been its *price*. Other types—the electric "buzzer," the exhaust, the bulb—have remained only because they could be made to sell for considerably less money than the Klaxon or Klaxonet.

No one denies that the Klaxon and Klaxonet are the best warning signals that it is possible to produce. No one has ever even *claimed* to make a signal as good. What they *have* talked is *price*.

No type or kind of signal on the market today can long withstand competition with this new—this MOTOR DRIVEN signal at *$12*.

Send in as many names as you wish—to reach us before July 15th—when selection is to be made. Mark envelope "Name Contest" and address it to the Lovell-McConnell Mfg. Co., 203 Wright St., Newark, N. J.

Deliveries will begin September 1st. No orders can be accepted prior to August 15th.

KLAXONET

Studebaker

The $800 Studebaker-Flanders "20"

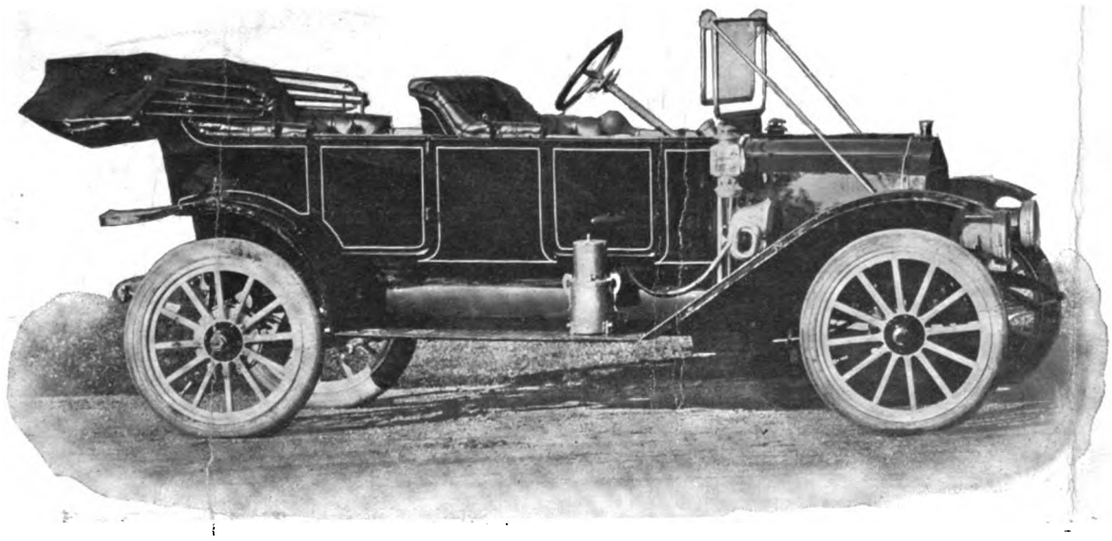
The Studebaker-Flanders "20" has a tremendous price advantage.

No other car, offering as much value approaches its price.

Think for a moment what you get when you buy a Studebaker "20."

It is a real car, modern throughout in design and construction, large enough, and so powerful that you will never find road conditions in which your Studebaker "20" cannot spin its wheels.

The motor is a marvel, very speedy, quick to pick up, flexible, the kind of a motor a driver grows to like and have full confidence in.



The Studebaker "20" transmission system is of the standard three speed type, any car speed you wish up to 55 miles an hour. The rear axle is remarkably well designed and built, giving the best of service.

Every Studebaker "20" body gets 17 coats of paint and varnish, which are properly rubbed and aged. If you take care of your car, your Studebaker body will equal any automobile body on the market.

These are some obvious points which show the car's value.

But the deeper you go into the design and manufacture of the Studebaker "20" the better you will like it. We watch every detail.

Every Studebaker "20" is built not only for the first mile but for the 20,000th mile. In those qualities which make for endurance and lasting satisfaction, the Studebaker "20" is incomparably first. Why? Because it is Studebaker-built, and Studebaker always builds that way.

Studebaker-Flanders "20" Touring Car, $800, f. o. b. Detroit.
Equipped, as above, with Top, Windshield, Prest-O-Lite Tank and Speedometer, $885.

NATIONAL MOTOR VEHICLE CO.

W.U.T. CODE. A.B.C CODE. (4TH EDITION)

Indianapolis, Ind, May 31, 1912.

Hartford Auto Parts Co.,

Hartford, Conn.

Gentlemen:

The Second Annual 500 mile International Sweepstake was won by DAWSON in a NATIONAL. This means more NATIONALS and more of your good material to build them.

We positively must have all the material due on our delivery specifications at once. We want June 1st material shipped June 1st. Ship it in at once so that the public can have all the NATIONAL CARS they are now demanding.

Please acknowledge this and tell us just what and when.

Yours truly,

NATIONAL MOTOR VEHICLE CO.

Thos. J. Moore

This advertisement is just a final echo from the Indianapolis Speedway. The fact that Joe Dawson's winning National was Hartford equipped is incidental—and only natural, because National cars are "quality" clear through.

The one big fact that stands out—one that we want every car manufacturer to know—is just this—

The National people kept hard after us for prompt deliveries—and we made good.

Costs Nothing to Operate

Let us emphasize once again the importance of absolute dependability in a warning signal. The perfect signal must never fail—not once in its entire life time. That once is sure to be the once that the warning was most needed.

The Long Horn can never fail. There is nothing about the Long Horn that could permit failure. No batteries to wear out. No motor to break down. No bulb to rot or crack. Nothing but a simple, positive, mechanically operated signal that must always issue its warning note if you but press the button. Glance at these photographs. They tell the story in themselves. Then write us for territory. Dealers will find that the Long Horn makes them both friends and money.

EXPERIENCE — SHELDON — RIGHT DESIGN
FACILITIES — AXLES — RIGHT STEEL

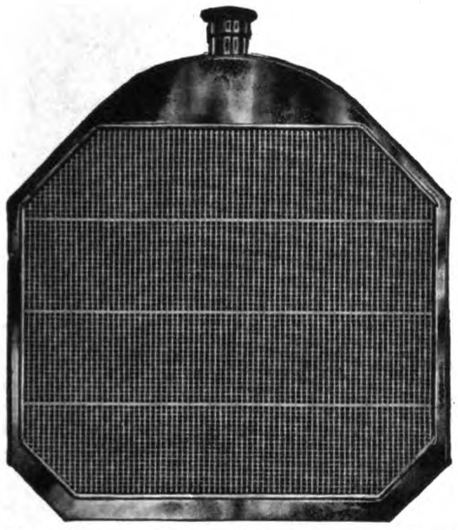
"Made in the Largest Axle Factory in the World"

Axle Talk—No. X

SHELDON quantity production does not presuppose automatic production which always allows the occasional faulty axle to get through the shops and on to the car.

SHELDON demand is growing, hence we must have quantity production—but we meet this increased demand with increased help in the inspection as well as in the mechanical force.

Every SHELDON axle must have its diploma before it is sent out to do the work for which it is designed and made. Before receiving this diploma its examination is severe.



Particular attention is paid to tests which must prove each axle capable of standing up against road shock, in its different phases, side thrust and a dozen and one causes which call for sturdy and continued resistance.

"Inspection of the individual axle by the individual" is the key note in SHELDON quality and our guarantee practically extends from the factory to the manufacturer and then to the consumer.

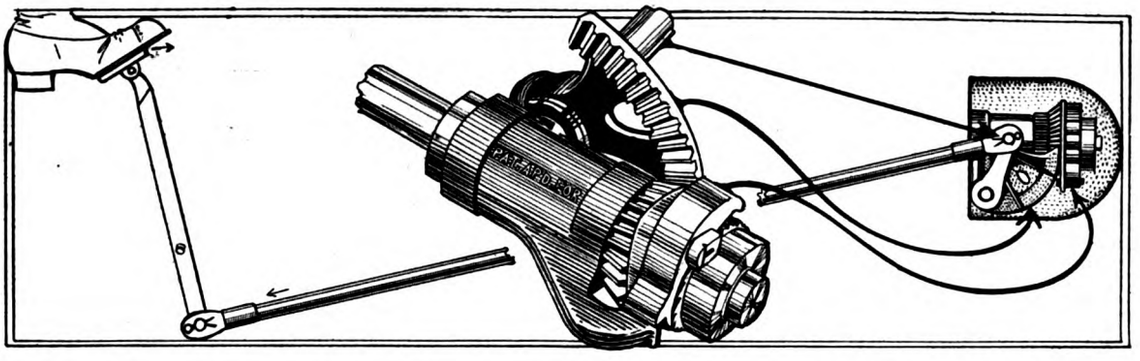
Are They Getting Back of the Cobwebs



Looks pretty much like it.

And it's just one of our predictions being fulfilled—possibly a little earlier than we anticipated.

Self starters that are going into the discard have inefficiency, over-production and price cutting to blame. **And inefficiency principally.**

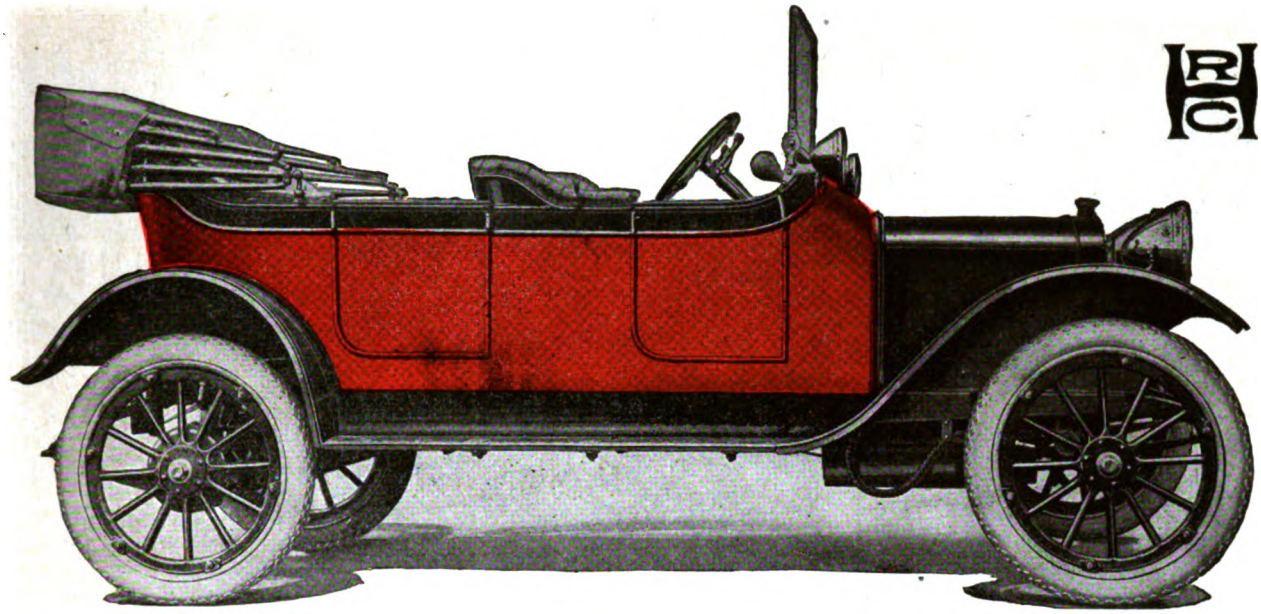
The National Starter was born out of the cumulative mistakes of designers in valves, tubes, wires, tanks, dynamos and the other ninety odd per cent "make good" devices.

And as the lower illustration shows, it is a strong, sturdy, **common sense** application of a primal **mechanical** principle.

That's why it must start the car every time you push the foot pedal.

There isn't much more to say—but here are two facts big with meaning:

The only unbreakable, dependable self starter must be purely mechanical.



The only perfected, tried and proven mechanical self-starter is the National Starter, illustrated here.

The price of the National Starter is $50.00 and it will give ten times more service and satisfaction to its user than any tangle of complications that ever coughed engine disorder into a cylinder. **More dealers wanted.**

NATIONAL GAS ENGINE STARTER COMPANY

One reason for Reliance quality

THIS picture illustrates one step in the manufacture of a Reliance Magneto Spark Plug. A skilled potter is working at a lathe with forming tool and calipers, turning the half-hard clay to microscopically exact proportions before it is sent to the ovens to be baked into our heat-defying porcelain. This skilled laborer and his fellow workers draw big pay and are worth it. They are one of the reasons why Reliance Spark Plugs are the best your money can buy.

Supreme in Oily Engines **Reliance MAGNETO PLUG**

The secret of the Magneto Plug's efficiency lies in two things—the high quality of the porcelain and the alloy of platinum and iridium we use for making the central electrode that carries the current. We make this porcelain in our own potteries, importing our clays and other ingredients from abroad; and we pay for our platinum and iridium a price higher than that of pure gold.

This central electrode is a **solid** piece of platinum-iridium. In ordinary practice a mere tip of platinum alone is used. Our electrode is baked in the porcelain by a secret process, which does away with cements, nuts, gaskets and the like, and absolutely prevents compression leakage.

Perfection in every detail has been our aim. A closed end has also been developed, which both gives greater stability to the entire plug and **makes it especially desirable where an excess of oil is used.** The price of the plug is $1.25.

Will you try a set at our risk? We will mail them prepaid on receipt of price and give you an ironclad guarantee of satisfaction or your money back any time you say. When writing, specify size wanted or make of car.

Our book, "Ignition and Spark Plug Talk"—every motorist ought to have a copy —mailed free for the asking. Write for it.

SPLITTING Hairs at the Timken Plant

It is literally necessary to split hairs to illustrate the extreme accuracy of the manufacture of Timken Roller Bearings.

An accuracy and care that came after Timken Bearings had won their way on the sheer merits of their unique principles of design alone.

TIMKEN
TAPERED ROLLER BEARINGS
are made with as much care as a watch

Take the gauging of the rollers for instance. Every roller in a Timken Bearing must be just the size of every other roller.

It would never do to trust the gauging of the rollers to human hands. Human liability to err is too great. The mechanical perfection of Timken Bearings is a matter of too much pride with us.

So we designed and built machines that take the rollers after they have been hardened and ground to the limit of human accuracy and sort them into lots in which every roller is the exact size of every other roller.

The machines do not err—they do not depend on human eyesight or judgment.

They distribute the rollers with unerring accuracy to different containers. The separation of the sizes is purely mechanical, and electrical. Electric contact decides which container each roller shall enter.

When the gauging is finished each container holds rollers of the same identical size. The containers are sealed till the workman assembles his bearings. Then he knows positively that every roller is right.

This is just one example of the care in making that assures you not only the bearing with all the correct principles of design, but the bearing that is built with the utmost accuracy.

This is one of the reasons why Timken Roller Bearings are giving such satisfactory service in the cars of the great majority of American pleasure and commercial car builders.

The list of Timken Users names nearly every good car that you know. Printed in a booklet called "The Companies Timken Keeps." Send for a copy today.

The Timken Roller Bearing Company
Canton, Ohio, U.S.A.

The only axle manufacturer licensed to make automobile axles equipped with Timken Roller Bearings is the Timken-Detroit Axle Company

SILENT Great Western FORTY 1913

Another Bullseye for 1913

Great Western Hits Highest Mark of Value

Last year we swung into the line of big sellers by a vigorous announcement of the advance 1912 features we had put into our car. This year we break all records by not only including a host of new up to the minute improvements, but also offer the 1913 Great Western, fully equipped **at $1,585 or $265 less than the previous model.**

With our increased output, cutting down factory expense, we are offering you a car at $1,585 which for beauty, power, speed, quiet operation, reliability, completeness and general all around satisfaction, compares with any $2,500 to $3,000 car in the world. It is not our policy to make only a few cars and charge you a big price for our name. Rather than that, we aspire to place dozens of Great Westerns in every community in the United States—owned by people who want the right kind of service and convenience out of their cars—but who are not averse to saving a thousand dollars or more at the outset.

The 1913 Great Western Touring Car

The 1913 line includes a Roadster, Four Passenger Touring Car, Five Passenger Touring Car and a Four Passenger Sedan for winter use.

36 x 4 inch tires
Demountable rims
Typhoon electric signal
Foot and robe rails
Tool box and tools

L head 4¼ x 5½ long stroke motor
Full 40 Horse Power
Accessible unit power plant
Enclosed valves all on one side
118 inch wheel base
Tire irons and extra rim
Gasoline tank gauge
Deep upholstering, hand-buffed leather
Invisible coil with lock switch
Jack, pump and tire repair kit

Full floating rear axle with large New Departure and Hyatt bearings
Large powerful double internal expanding brakes
Tie rod behind front axle
Cellular front radiator
Latest Remy magneto with kick switch
Easy riding Vanadium steel springs
Handsome body, deep blue color, black walnut trimmings, 18 processes of body finish

Nearly everybody has heard of the Great Western's wonderful record as official pathfinder, prize hill climber, and official selection by the U. S. Government for Indian service in the West. These facts are absolute proofs of quality. Send for new 1913 catalog telling in detail all about this handsome, trustworthy car. A complimentary subscription to *The Tattler*, our interesting little monthly magazine, also on request.

Dealers: **There's a great big sales activity stirring everywhere for the Great Western. It has the quality that attracts attention and makes people decide to buy. Our 1913 organization is being extended to cover every live town in the United States. We can take on a few more hustling dealers who want to handle a fast selling car. Write today.**

The 1913 Great Western Roadster

The 1913 line includes a Roadster, Four Passenger Touring Car, Five Passenger Touring Car and a Four Passenger Sedan for Winter use.

CHAMPION

TRADE-MARK

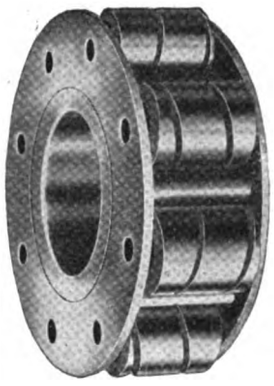
Champion Spark Plugs

CHAMPION X
75 Cents

Champion spark plugs are built by machinery found in no other plant. We assemble each plug in a way that permits no leakage. This is the secret of Champion superiority.

Out of every 100 cars made in 1912, 60 are Champion equipped. Our production for 1913 will be greater than ever. It is the result of Champion maximum satisfaction.

Twenty-five per cent of the manufacturers of the United States specify Champions. This means Champions have stood the test of road and laboratory. The two largest producers, Ford and Overland, call for Champions. Such demands have made our factory the largest in the industry.



You always buy up-to-date Champions. Dealers who find a preference for one style are urged to exchange others. They come in a box bearing the "World" trade mark.

Manufacturers and agents, write today.

Axle Design

SEVEN COSTLY CARS from factories of seven different well known car builders were exhibited at recent shows with semi-floating axles. These cars were priced at from $2,000 to $6,000, with five of them over the $5,000 mark. If this type of axle were good only for the cheaper cars would the above facts be possible?

THE ESSENTIAL DIFFERENCE between a "semi" and any other form of floating axle is that the bearing at the wheel hub is inside the axle tubing instead of outside. No matter what the construction, the parts which carry the weight of the car and transmit the power are made sufficiently strong to do their work. This is what interests the user.

WITHDRAWABLE AXLE SHAFTS can be made a feature of a semi-floating design as well as of any. Other features also are interchangeable. And always it must be remembered that a real full-floating job requires two bearings in each wheel—or twice the number of bearings to increase production costs.

AN INCREASING DEMAND finds many cars now equipped with the "single bearing" type of floating axle. Properly this is called "three-quarter floating." It supplies at once an economical and high class construction. One bearing is used in each wheel and the bearing is placed outside the axle tubing.

DOES YOUR SALESMAN EXPLAIN who makes the axles, their details of design and why they are strong enough to stand the strain? Does he describe the bearings, telling why they are best for the purpose, and that behind them stands a firm's admitted reputation for fair dealing? Or does he simply point to the axle and try to dismiss the whole subject with the one term "full-floating"?

THERE WAS A TIME when any popular catchword would sell a car. Conditions have changed 'til now the purchaser is as wise as the salesman. He knows there are bearing makers who have grown up with the business and who have been successful for three reasons: First, their product is theoretically right; second, it is made right, and third, its users are treated right.

REGARDLESS OF DESIGN in its relation to axle types, he knows that Hyatt Flexible Roller Bearings in an axle spell complete satisfaction to him as an owner.

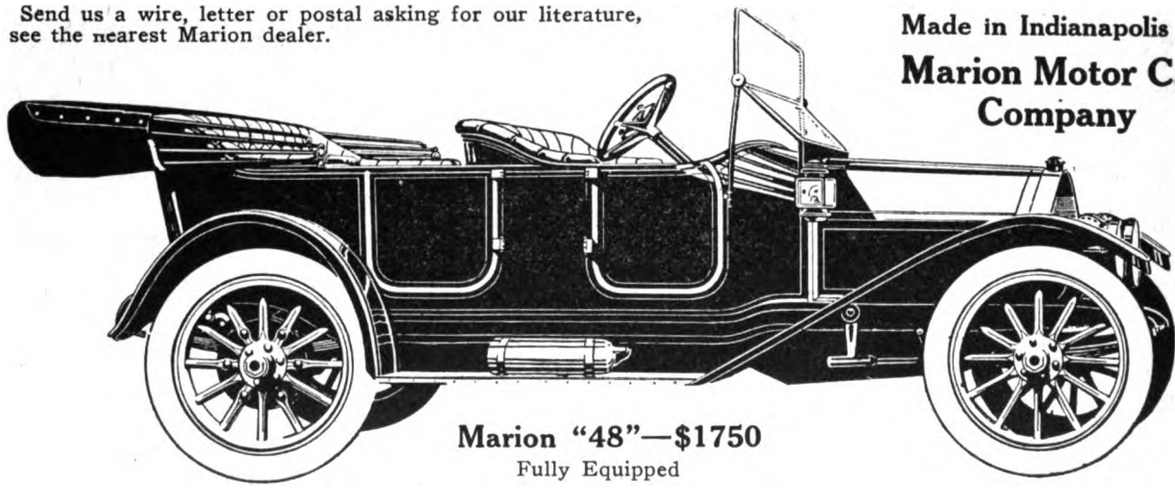
Marion

Expansion Follows Satisfaction

TEN YEARS of making good at a fair price forces the expansion of the Marion Motor Car Company. We built our first cars well. We built better cars each succeeding year. Now we have plans for the greatest Marion of all. Marion age, Marion quality and Marion reputation have combined to make urgent an increased production. We recently announced our plans. They are nearing cimpletion Numerous men of national prominence as producers are now with us. Factory facilities are broadened. We are ready to make the greatest Marion of all.



To buy because of low price is unwise. To pay more than necessary is to yield to pride. The Marion is the medium. It is a good car at a fair price. It performs constantly and economically year after year. It doesn't have to be "traded in."

Ten year old Marions are doing valiant duty today. This year's models all have the Marion sturdiness and efficiency of old, but they also have every refinement and improvement automobile engineers have produced since.

In other words, the MARION is a good car, a time-proven car, a modern car. It is sold at a price that suits the man or woman who demands a genuinely good and serviceable automobile in exchange for the exact amount of cash it is worth.

Send us a wire, letter or postal asking for our literature, or see the nearest Marion dealer.

Made in Indianapolis by
Marion Motor Car Company

Marion "48"—$1750
Fully Equipped

Five-passenger, fore-door touring; forty-five horsepower; motor, 4⅛ x 5½; wheel base, 120 inches; tires, 36 x 4 quick detachable; nickel trimmings throughout. $1750 includes equipment as follows: **Fine mohair top and curtains; fine mohair and rubber top boot; Zigzag plate glass wind shield; $50 Warner speedometer; Prest-O-Lite self-starter; Prest-O-Lite tank; full set five (5) lamps; full set tools, repair kit, etc.**

Model "Thirty-Seven," $1350
Fully Equipped

Five-passenger, fore-door Touring; Forty horsepower; motor, 4 x 5; wheel base, 112 in.; tires, 34 x 4, quick detachable. $1350 includes equipment as follows:

Fine mohair top and curtains; fine mohair and rubber top boot; $50 Warner speedometer; genuine plate glass wind shield; Prest-O-Lite self-starter; Prest-O-Lite tank; full set five (5) lamps; full set tools, repair kit, etc.

"Bobcat" Roadster (Model Thirty-Six) $1350
Fully Equipped

Two-passenger Roadster; forty horsepower; motor, 4 x 5; wheel base, 112 in.; tires, 34 x 4, quick detachable. $1350 includes equipment as follows:

Fine mohair top and curtains; fine mohair top boot; rubber driving apron rolled on dash; $50 Warner speedometer; Prest-O-Lite self-starter; Prest-O-Lite tank; full set five (5) lamps; full set tools, repair kit, etc.

Inspecting Fabric for Firestone Tires

"Firestone"

RIGID inspection of the matchless material used by the world's most skilled tire builders—that's the secret of Firestone unchallenged leadership.

An idea of how thorough this inspection is, how high grade the material used, may be had from the illustrations. Fabric is the backbone of every worth-while tire. Fabric alone in

Firestone

Smooth Tread and Non-Skid Tires

would place them in a class apart. The finest combed Sea Island cotton is used. Yet even of this sturdiest of materials many carloads are thrown out because they cannot pass the test. Before fabric is worthy of Firestone use, *it must show a resisting strength several times greater than any possible road strain.* Every roll is tested again and again and every yard inspected, inch by inch. Imperfections cannot creep in; Firestone Tires cannot "let down."

This unprecedented care is followed through every detail of manufacture. It costs more to build Firestone Tires, but their extra mileage *built in* under titanic tests and infinite inspection, assure to all users

ANNOUNCEMENT

1913 Pleasure Models

"If you have never driven one up a hill,
You have missed half the sport of motoring!"

A Knox Little Six—Model 46

A new distinctive car of unusual power, quietness, comfort and style, embodying the most advanced American and European ideas in approved design and construction. Among the important features of Model 46 are the V-shaped radiator, silent chain driven cam and magneto shafts, option on right or lefthand steer and unusual provision for taking up wear and preventing noise. **"The Car of Surprising Economy."**

Motor 6-cylinder, 4⅛" x 5½". A. L. A. M. Rating 46 H. P.
Wheel-base 130". Tires 37" x 5".

Price with all Open Type Bodies and Complete Equipment.....$4350
Price with Limousine Type Bodies and Complete Equipment..... 5350
Price with Landaulet Type Bodies and Complete Equipment..... 5400

60 H. P. Six—Model 66

An ideal, powerful, spacious family car, incorporating the famous Knox 6-cylinder motor in its fourth year of refinement without radical change.

Motor 6-cylinder, 5" x 5½". A. L. A. M. Rating 60 H. P.
Wheel-base 134". Tires 38" x 5½".

Price with all Open Type Bodies and Complete Equipment.....$5000
Price with Limousine Type Bodies and Complete Equipment..... 6200

4-Cylinder—Model 44

The lightest Knox model. Trim, comfortable, a powerful hill climber, quiet and flexible, embodying the famous Knox motor in its fifth year of service without important change.

Motor 4-cylinder, 5" x 5½". A. L. A. M. Rating 40 H. P.
Wheel-base 117" and 122". Tires 36" x 4½".

PRICES, COMPLETELY EQUIPPED

2-Passenger Raceabout	$3300	7-Passenger Touring Car	$3550
Double Rumble Raceabout	3350	5-Passenger Touring Car	3500
4-Passenger Torpedo	3400	2-Passenger Coupe	4300
5-Passenger Torpedo	3450	Limousine	4400

4-Cylinder—Model 45

Longer body and wheel-base than Model 44. A roomy, comfortable family car. An ideal chassis for spacious, open and closed types of bodies.

Motor 4-cylinder, 5" x 5½". A. L. A. M. Rating 40 H. P.
Wheel-base 126". Tires 37" x 5".

Price with 6-Passenger Open Bodies and Complete Equipment.....$3700
Price with 7-Passenger Open Bodies and Complete Equipment..... 3800
Price with Limousine Bodies and Complete Equipment..... 4700

Knox 4-cylinder models are completely equipped, including electric side and tail-lamps with storage battery, acetylene starters and automatic gas lighters for headlights.

Knox 6-cylinder models are regularly equipped with self-starters and dynamo lighting systems.

Send for Folder with Detailed Specifications.

Hartford Pointers—No. 5

More Tire Mileage—and Easy Riding

IF greater tire mileage is what you seek, learn how the Truffault-Hartford Shock Absorber prolongs the life of tires.

Tires are short-lived, because of the abuse they receive.

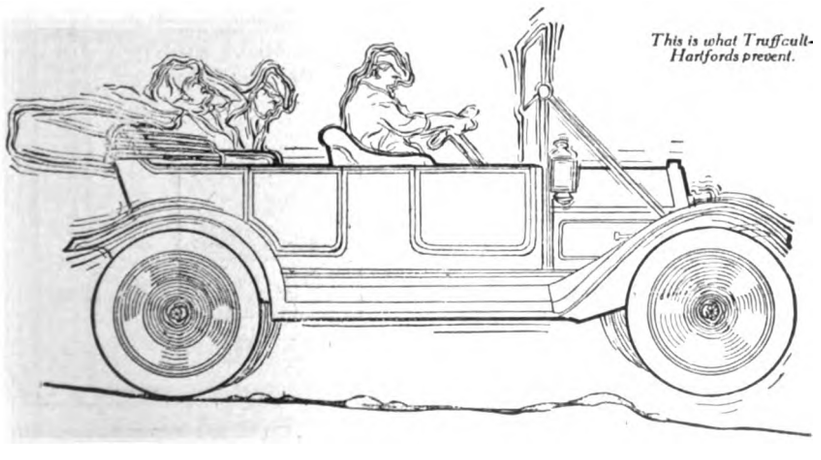
From the very nature of their construction, they cannot withstand thumping and bumping over rough roads.

How to provide against this ill-use is a question only the Truffault-Hartford Shock Absorber can decide.

This device does away with the thumping and bumping by providing a proper control to the springs. It keeps the wheels of the car constantly on the ground, thereby eliminating the jumping of tires caused by e..cessive spring action and rough roads. But the utility of the

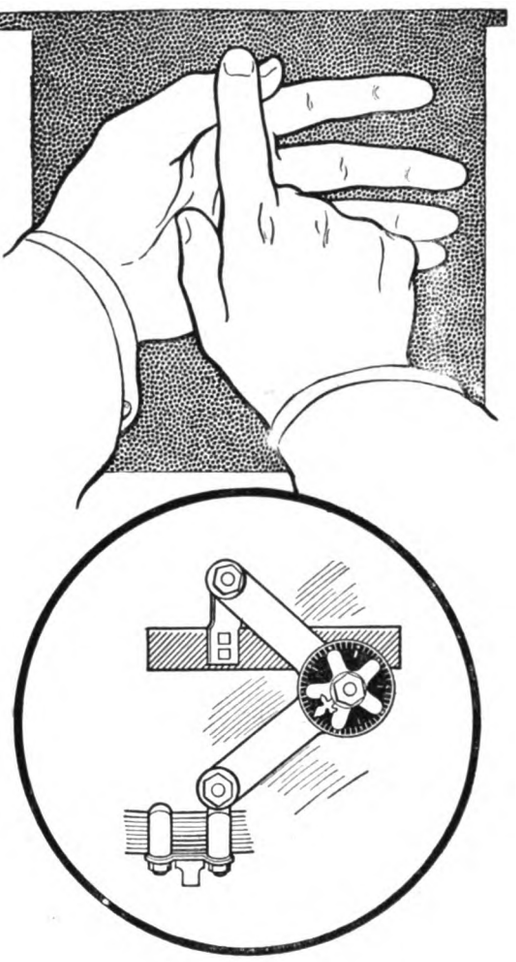
Truffault-Hartford SHOCK ABSORBER

is not confined to tire-saving alone. It is invaluable to economical upkeep and easy riding. Through the perfect control it exerts over spring action, wear and tear on the engine and parts is greatly reduced—vibration minimized—and the jolts and jars of traveling over rough roads effectually combated.



The improvement the Truffault-Hartford works in the riding qualities of a car is not to be recorded in mere words. You must ride in a Truffault-Hartford-equipped machine, over roads of your own choosing, to realize how great is the benefit conferred by the use of this device.

In the Truffault-Hartford, the chief objection to shock absorbers is overcome. This device assuredly *does not* lessen the flexibility of the spring. The rotary friction principle upon which it is built reveals the reason.



Rotary friction, as applied *only* in the Truffault-Hartford, means a slight but constant frictional resistance to *both* the downward and upward movements of the spring—such a resistance as allows for the normal full play of the spring at all times, but prohibits the spring operating outside of its normal working limits.

Twenty-four of America's leading cars carry Truffault-Hartfords as regular equipment—a fact of no little significance to the man who would use the equipment sanctioned by America's foremost automobile builders.

Four Models—$60, $45, $25, $15.

This is what Truffault-Hartfords prevent.

Ask your dealer for further information and write us for our handsome illustrated catalog which embraces many other valuable points impossible to cover in an advertisement. Write for it today.

Spring action being necessary to secure easy riding, auto owners should avoid so-called shock absorbers working on the **eccentric** cam and **wedging** principles. Such devices limit the play of the spring creating a condition undesirable, if not actually dangerous.

"The Horn that's Made for the Discriminating"

TUTO HORN

THE TWO TONE HORN

Best All Round Warning Signal.

THERE are many electrical warning devices on the market, all claimed by their respective makers as the best.

¶ We do not take issue with these claims, for some particular warning device might be considered best for a very limited service, and by those not completely versed in the art.

¶ The TUTO Horn is not limited in its operation to fit some particular condition. It is a complete warning device and does all of the signalling for the car.

¶ It is the only warning signal that produces two distinct service notes, one of low abrupt character for regular use, replacing the inadequate bulb horn, and a louder tone for emergencies.

¶ The low note of the TUTO Horn gets the right-of-way 90% of the time and without undue disturbance—courteous and economical in operation.

¶ Unlike the bulb horn, supplemented by the one-loud-note electric horn, the TUTO Horn allows the driver to go from low to loud instantly and without moving a hand, simply the giving of a further pressure on the same button that is used in producing the milder signal.

¶ This makes the TUTO Horn absolutely safe in case of emergency, no confusion, no extra mental effort necessary when every thought must be directed to the controlling of the car. The act of gripping the steering wheel, as danger approaches, forces the thumb clear down on the TUTO button, automatically demanding attention with the loudest tone of the horn.

¶ Close range service is most vital in the saving of life, limb or property. At a distance the car driver has time to think and act and most any one-note warning device will serve the purpose.

¶ The TUTO Horn is fitted for all conditions and is pronounced, by those who know, to be the only real emergency signal.

¶ In addition to these superior service values, the TUTO Horn is the only warning device which comes complete with special fittings for making a most neat and permanent job of installation on any car. It is best to use the TUTO Horn for standard equipment and it is not out of place to request that the TUTO be furnished on your new car

McCue axles and McCue wire wheels mean the greatest advancement in car design and construction. McCue axles are so built that they will admit of the use of either wire or wooden wheels on the same spindle.

This simplifies matters for the manufacturer, because he can now offer either wire wheels or wooden wheels as optional equipment without interfering with his design or manufacture in any way.

The general public is beginning to realize as well as you that wire wheels are here to stay, because wire wheels mean greater tire life as well as greater car life. Abroad they are more common on cars of class than wooden wheels and nearly all the prominent foreign racing drivers use wire wheels.

McCue Axles Are Dependable Axles

The entire load is carried on the housing, which is made of sheet steel, one piece from end to end, without tubes, telescoped into the ends for spindles. The shape of the housing is such that it is a truss within itself and so constructed as to allow a factor of safety of 20 to 1, before even bending.

The brake adjustment is strictly our own, so designed that when once the brake rods are properly adjusted they need never be disturbed again. This is accomplished by the use of adjusting cams at the rear of the drums. There is sufficient adjustment in these adjusting cams to allow for the complete wearing out of the brake lining.

The Easiest Riding Car In The World

The MARMON SIX

Six Cylinders—4½ in. Bore, 6 in. Stroke, 48-80 Horse Power—$5000 Fully Equipped.

Announcing The Marmon Six

In announcing the Marmon Six we will say that so far as any test can be applied it is a proven car—a car that will live up to the reputation of the Marmon name.

During the years the Marmon Six has been under development and test—in the shop, in road service and in many of the world's most important races—we believe we have overlooked nothing that would add to the quality and capability of the car or that would enhance the safety, the comfort or the convenience of its user.

Its mechanical superiority and durability, its even balance, its ease on tires, the efficiency of its lubrication, its power and smoothness of operation, have been proven by such tests as the winning of the 200 mile Wheeler-Schebler Contest on May 30, 1910, and the First 500-Mile International Sweepstakes race, May 30, 1911. In these contests a Marmon Six was pitted against the largest and most representative field of European and American cars ever entered in any race and in both events the Marmon won.

Among its many new and exclusive features is the lubrication by means of the Marmon system of automatic force feed, delivering oil not only through the hollow crank shaft but also to the cam shaft bearings through hollow cam shafts. The front axle is another new and distinctive feature first introduced with this model. The vertical spindle is placed directly in the center line of the wheel making the surest, safest and easiest steering mechanism ever devised. It permits this car with 145-inch wheel base to be turned in a forty foot street. Other original and effective mechanical improvements are incorporated—every one of which has been tried and proven up to the Marmon standard of excellence.

The thorough equipment leaves nothing to be desired in the way of convenience for the motorist. It includes a cape top, new type wind shield, self-starter and dynamo electric lighting system, electric horn, speedometer with clock, shock absorbers front and rear, power tire pump, tire carrier, extra demountable rim, coat rail, foot rest and tool equipment.

The bodies with their graceful, symmetrical lines, their deep and luxurious upholstering and the many refinements, added to the strength of the Marmon perfected cast aluminum construction, are the best examples of the art of body design and building. There are seven, five, four and two passenger types—the price, f. o. b. factory, Indianapolis, is $5000 with full equipment. Limousine, $6,250; Landaulet, $6,350.

The Easiest Riding Car In The World

The MARMON "32"

Four Cylinders—4½ in. Bore, 5 in. Stroke—32-40 Horse Power—$3000 Equipped.

Announcing a New Series of The Marmon "Thirty-Two"

The features which in the past have built up so great a name for the superiority of Marmon design, materials and construction are not materially changed in this new series of the Marmon "Thirty-Two."

It is moderate in size and capacity, light in weight with an abundance of power, exceptionally well proportioned and well balanced and will meet every requirement of city use and touring with the greatest comfort and economy.

The motor remains unchanged except for the addition of an electric lighting dynamo. The clutch pedal has an adjustment and increased leverage of the clutch throwout. The brakes, which have already received the highest praise from experts, are even further improved by a combination facing of asbestos fabric lining and composition metal in alternate segments on the brake shoes. An improved, simple brake adjustment has also been added which gives another point of Marmon superiority in its extreme accessibility and effectiveness. This is a new and distinctive feature brought out with this new series and the Six.

The equipment furnished with the new series of the Marmon "32" consists of: Pantasote Cape Top, dust boot, improved Marmon special ventilating wind shield, speedometer with clock and electric light, horn with bulb on steering column, dynamo electric lighting system with storage battery, electric headlights, combination oil and electric dash and tail lights, self-starter with Prest-O-Lite Gas Tank, shock absorbers on rear, extra demountable rim, single tire carrier, coat rail, foot rest, jack, pump, tire repair outfit and compelte tool equipment.

The five passenger Touring and four passenger Suburban bodies have extra deep rear seat cushions which give an added luxury and comfort. Either body type with equipment as above, $3,000 f. o. b. factory, Indianapolis.

Roadster type with single rumble seat or trunk and with top and complete equipment, $2,900. Speedway type speedster without dash lamps, top or windshield, but with shock absorbers front and rear, double tire carrier and extra rim, $2,850. Limousine $4,000, Landaulet $4,100.

THE MOTOR WORLD

Vol. XXXII New York, U. S. A., Thursday, July 11, 1912. No. 3

MAY FORM FOUR FOREIGN COMPANIES

De Lisser's Visit to Europe Fraught With Far-Reaching Importance—Tire Situation Has Aroused Car Makers.

Having resigned the vice-presidency of the United States Motor Co. and returned to his earlier love, the Ajax-Grieb Rubber Co., as chairman of its board of directors, Horace De Lisser now is preparing to sail for Europe on the 30th inst. It first was stated that the purpose of his business is to forward plans for the establishment of an Ajax tire factory in Europe, but later and authentic information makes clear that De Lisser's plans reach much further and that, instead of one foreign factory, four of them are within the realm of probability, one each in Great Britain, France, Germany and Belgium.

It appears that abroad the "take it or leave it" policy largely prevails, three tire manufacturers practically controlling the trade of Great Britain and the entire Continent. They are so strongly intrenched that no guarantee attaches to their tires, and in many respects it is difficult to budge them—so difficult that, having become cognizant of the origin of the Ajax-Grieb Rubber Co. and what it had accomplished in this country, certain of the automobile manufacturers have made overtures to the Ajax-Grieb people to undertake similar enterprises abroad. The overtures are of a well-defined nature, but the outcome naturally depends largely on the results of De Lisser's pending visit.

The Ajax-Grieb Rubber Co., as will be recalled, grew out of a somewhat strenuous, if not arbitrary, situation which prevailed in the tire trade in this country. Believing that the tire manufacturers were too greatly in agreement in respect to prices and policies, and too unbending generally in their attitude toward large buyers, the Maxwell-Briscoe Motor Co., the Ford Motor Co. and others became stockholders in the Ajax-Grieb enterprise and in this way gave it an immediate foundation and a ready market for its products. Its success, naturally, was instantaneous and continued.

The foreign automobile manufacturers whom De Lisser will visit believe that a tire company, if not four of them, similarly organized, can be made as profitable in Europe as in America. It is understood that if present plans come to a head, these manufacturers will subscribe 50 per cent. of the stock in the Ajax foreign corporations.

Abbott's Head Succumbs to Long Illness.

After an illness of about one year, Charles W. Jamieson, president of the Abbott Motor Co., of Detroit, Mich., died at his home in Warren, Pa., on Saturday afternoon last, 6th inst. Jamieson first became identified with the Abbott Motor Co. at the time of its reorganization about two years ago, at which time he invested heavily in the stock of the company and was made its president and became a really active worker, being chiefly instrumental in further developing the company. In addition to his interest in the Abbott Motor Co., Jamieson was one of the largest independent oil refiners in the country, was president of the National Bank of Warren, Pa., and was heavily interested in other mining and manufacturing corporations. The management of the Abbott Motor Co. will remain unchanged and for the present will be in charge of F. N. Knapp, a director, who has directed the Abbott affairs during Mr. Jamieson's illness.

Simms Here to Assist Reorganization.

The reconstruction of the Simms Magneto Co. of Bloomfield, N. J., the control of which company some three weeks ago passed into the hands of men closely identified with the Assets Realization Co. of New York City, at which time details of the transaction were published in the Motor World, is expected to take tangible form within the next few days, President F. R. Simms having arrived from England, where he resides. The purpose of his visit is to attend a meeting of the stockholders which has been called for to-morrow (Friday), when, it is expected, a definite plan of action will be reached.

DURANT AGAIN IS "DOING THINGS"

Forms $65,000,000 Corporation With Ten State Subsidiaries—Each Will Manufacture Little Cars, Including "Six" at $1,000—Chevrolet Car Involved.

W. C. Durant is again on the road to complete happiness. It is no secret that since the control of the $40,000,000 General Motors Co., which he organized, passed out of his hands Durant has been restless—so restless that, while remaining a director and vice-president of the General Motors Co., he has placed irons of his own in the fire, among them the Chevrolet Motor Co., in Detroit, and the Little Motor Car Co., in Flint, Mich.; and these properties, it now transpires, are to form the basis of a $65,000,000 corporation which, to all practical purposes, will be Durant's own. It will be styled the Republic Motor Co., and Durant will be its vice-president and general manager. It is being incorporated under the laws of Delaware and is one of those immense projects which seem essential to Durant's happiness.

Despite the size and far-reaching character of the enterprise, Durant has been uncommonly successful in keeping the details to himself. For the Delaware corporation is to be the mother of ten other corporations located in as many states and bearing the same name. The first of them, the Republic Motor Co. of New York, was practically completed late last week, when it was incorporated under the laws of New York with nominal capital of $500, which, however, shortly will be increased to $1,500,000. It already has secured a large plant in New York City, where, under license of the Little company, the Little cars—a runabout at $715 and a six-cylinder touring car at $1,000—will be reproduced in New York City itself. The Republic company will have also the exclusive selling rights to the Chevrolet "sixes," which, however, will be produced only in Detroit. The property purchased covers the entire

Digitized by Google

block on Eleventh avenue between 56th and 57th streets, part of which was occupied by Rothschild & Co., the once well known body builders. The contract for remodeling the plant has been let and the work is well under way. When completed, the Republic Motor Co. of New York will be possessed of floor space equal to 111,341 square feet.

Similar plants are to be established in Philadelphia, Boston, Cincinnati, St. Louis, Minneapolis, Kansas City, Portland, San Francisco and Los Angeles, each of which, as previously stated, will be operated by a separate company bearing the name Republic and making Little cars, but all of them subsidiary to the parent Delaware organization.

In addition to the New York company, the Michigan company also has been incorporated. It is styled Republic Motors of Michigan and is nominally capitalized at $2,000, of which Durant holds four shares, R. T. Armstrong, of Detroit, four shares, and Theodore G. Sprague two shares. Armstrong is president of the J. B. Armstrong Mfg. Co., of Flint, which makes automobile springs, and Sprague is one of the mechanical experts of the Chevrolet Motor Co.

Durant still remains vice-president of the General Motors Co., but he now makes New York his headquarters, and while he freely and courteously confirms the general outline of his plans, as it is here detailed, he very courteously but more firmly declines to give the names of any of his associates in the huge enterprise. He admits that he will be vice-president and general manager and have direction of the entire project, but until the officers of the several companies are elected, which will come to pass within a comparatively short period, he will say nothing concerning the men he has gathered around him. He did admit, however, that the officers of the ten subsidiary companies will be men drawn from the States in which the plants will be established, but more than this he will not say regarding that phase of the matter. He also made clear that the ten plants are to be not mere assembling institutions, but complete factories. They will manufacture or purchase such parts as are required for the Little cars exactly as the Little company itself now purchases or manufactures them. In other words, the ten factories will not draw their supplies from the Little plant and the cars they produce will incorporate particular features or particular equipment that may be in demand in their respective territories. "Built on the Spot" is to be the Republic slogan, it being Durant's idea that most of the waste and much of the expense incident to the marketing of automobiles can be eliminated. As he expresses it, the problem to-day is not production but distribution. He believes he has solved it.

After the control of the General Motors Co. passed to other hands, it was fairly well known that Durant sought to effect a merger of several large and prominent companies whose names are almost household words in the automobile industry, but he failed to receive sufficient support or encouragement and the undertaking apparently has been abandoned; but grown used to doing large things in a large way, he quietly set about organizing a big company of his own, the Republic Motor Co. being the concrete result. Its proposed capital, $65,000,000, is so huge as to suggest that Durant has not wholly lost sight of the possibilities of future mergers, but on Tuesday last when he was asked point blank whether the Republic Motor Co. would include any other company or companies, or whether anything of the sort was in view, he promptly denied intentions of the sort, stating that the parent Republic company, which will be the $65,000,000 organization, will be composed wholly of the ten Republic companies which are to be organized in the several states.

The Little and the Chevrolet cars, which constitute the Republic backbone, are of the sort that cannot fail to command notice. Both will be listed at popular prices. The figures, particularly as they apply to "sizes," which now loom so large, are likely to exert no small influence in the trade. The Little "four," a 20-horsepower, two-passenger runabout, already is being marketed, lists at $690 f. o. b. Flint or $715 in New York, while the Little "six" touring car, which is being made ready, will sell for the astonishingly low price of $1,000. The Chevrolet car will be made in two models, both "sixes," a little one and a big one. The Chevrolet "little six" will list at $2,000, fully equipped; the price of the larger model has not been definitely settled. The former is just about ready for the market, and it is not too much to say that it is a truly impressive creation; it is splendidly designed and splendidly made, and includes several novel features that are certain to attract general notice.

Locomobile and Stearns Stiffen Prices.

Apparently the Packard company will stand the only manufacturer of high-priced products to reduce prices, for both the F. B. Stearns Co., Cleveland, O., and the Locomobile Co. of America, Bridgeport, Conn., whose products are well known as rightfully belonging among the "upper ten," so to speak, have made slight increases in their prices. The Locomobile company has added $100 to the list of its four-cylinder model and its small six-cylinder model, which henceforth will list at $3,600 and $4,300, respectively, and $200 to the list price of its large six-cylinder model, which heretofore sold for $4,800. In the case of the Stearns company, the increase has been more substantial, the reason being, it is given out, that the cost of materials and labor is attempting to keep pace with the soaring prices of foodstuffs and other commodities which come under the general heading "cost of living." Last year the list price of the chassis mounted with any type of open body was $3,500; this year the two-, four- and five-passenger open cars list at $3,750 and the seven-passenger car at $3,900. In keeping with the high quality of workmanship and finish, to say nothing of the actual size of the car itself, the price of the recently added Marmon "six" has been set at $5,000, thus marking the entry of the Nordyke & Marmon company into the ranks of the manufacturers of high-priced cars.

Asks $10,000 for Broken Contract.

Two years as dealer in New York and vicinity for the Niagara Lead & Battery Co., of Niagara Falls, N. Y., is worth $10,000, according to an action now on the general calendar of the Supreme Court for New York County, wherein A. H. Green, of the A. Hazen-Green Co., 1686 Broadway, asks that amount, alleging that his contract as dealer in the company's storage batteries was cancelled by the Niagara Falls concern. The contract in question was for three years, so the complaint alleges, and was permitted to run but about one year, being terminated in the summer of 1911. Meanwhile, Green is busy with other accessories and devices, while the Niagara business is now in other hands. Green states that he had the Niagara business on the way to a large development when the contract was revoked.

Disputed Bill Leads to Attachment.

Albert Martinez, as the assignee of the Vanguard Mfg. Co., of Joliet, Ill., on Tuesday last, 9th inst., served an attachment upon the United States Motor Co., of New York. The amount involved is $3,748.21, covering a bill for Vanguard windshields. Benj. Briscoe, president of the United States Motor Co., states that the amount represents a disputed account and that it will be taken care of in due course by the company's legal staff, and is without other significance than that a creditor permitted himself to become unduly exercised.

Hood Leaves Factory to Join Retailers.

Wallace C. Hood, whom Paul Smith replaced as manager of the Everitt Motor Car Co. of Detroit, has acquired an interest in the firm of J. S. Harrington & Co., 589 Boylston street, Boston, and already has removed to that city to take up his new work. The firm, which maintains branches in Providence and Worcester, handles the Everitt car in New England, so that Hood's duties will not be wholly strange to him.

Weed Enjoins a Connecticut Jobber.

On the application of the Weed Chain Tire Grip Co., of New York, the Federal court in Hartford last week temporarily enjoined Henry Horton, a New Haven (Conn.) jobber, from selling the Whittier chain tire grip, made by the Whittier Chain Tire Grip Co., of Boston. The Whittier grip is "anchored" with leather straps and is claimed to be an infringement upon the Parson-Weed patent.

EDWARDS COMPANY INCORPORATED

Capitalized at $2,000,000 and C. G. Stoddard Chosen President—Factory To Be In Vicinity of New York City.

After several months of careful preparation, during which time unfounded rumors concerning the plans of the company have been particularly plentiful, the Edwards Motor Car Co. at length has been duly incorporated, the papers bearing the seal of the State of Maine. The amount of the capitalization is $2,000,000, of which $750,000 is preferred and $1,250,000 common stock. As was to be expected, C. G. Stoddard, who has been the principal moving spirit in the venture, is president; H. J. Edwards, his colleague, is vice-president and general manager, and John F. Campbell, who formerly was treasurer of the Dayton Motor Car Co., with which company both Stoddard and Edwards at one time were intimately connected, is secretary and treasurer of the new company.

Though production plans covering the Knight-engined pleasure and commercial vehicles which the company will manufacture are well in hand, it is still undecided exactly where the factory will be located. It has been definitely settled, however, that the plant will be in the immediate vicinity of New York City. Sites in both Long Island City and close by in New Jersey are now being considered, though it may be several weeks before one or the other is chosen. It is planned eventually to produce both the pleasure and commercial vehicles in the same factory in order to center activities, though as was told three weeks ago in the Motor World, the production of trucks already has commenced in the factory of the Longest Bros. Co. in Louisville, Ky., which plant, together with patents and equipment, recently was acquired by Stoddard and Edwards for the purpose. Not more than 25 vehicles will be completed at Louisville, however. The active production of both types of vehicles will be commenced in the new plant in the East immediately it is acquired, and so far along are plans that it is expected that both cars and trucks will be ready for early Fall delivery.

Prest-O-Lite to Take New Tack.

Having had more rather than less success with its legal battles to establish its patent rights to the manufacture and refilling of its tanks, the Prest-O-Lite Co., of Indianapolis, Ind., now contemplates action of an entirely different nature, this time prosecuting under a statute which forbids the refilling of a trademarked container, such as labeled whiskey bottles, tobacco bags, etc., it being held that the Prest-O-Lite tank comes within this limitation. Hitherto actions for refilling have been for infringing the Prest-O-Lite patent, No. 664,383, but since a recent decision by Judge Kohlsaat in United States District Court in Chicago held that the patent in question has expired, the opponents of the Prest-O-Lite concern have believed they have some chance at law, even though numerous other high courts have decided contrary to Judge Kohlsaat, and it is expected that refilling therefore will be more frequent. Papers are being prepared by Winter & Winter of New York City, and the first actions will probably be begun within a few days in New York. Each penalty is a fine of $100.

Mott and Hayes Form Rim Company.

Although the Mott Wheel Works, of Utica, N. Y., has not established a branch factory in Jackson, Mich, as rumor had it, Otis W. Mott and C. B. Williams, of that company, have joined with Clarence B. Hayes, Winthrop Withington and Mark Merriman, of the Hayes Wheel Co., of Jackson, and have formed the Jackson Rim Co., which is capitalized at $100,000, and of which Mott is president, Hayes vice-president, Withington secretary and Merriman treasurer. The new company will locate in the Michigan city for which it is named, though just where the factory will be located has not yet been definitely decided. Though several of the men whose names are linked with that of the new company are intimately connected with the Mott Wheel Works, emphasis is laid on the fact that the Jackson Rim Co. is a distinct corporation and is in no way connected with any other company. As its name implies, it will specialize in the making of metal rims and other small parts.

Receiver Seeks to Sell Atlas Plant.

Fred. C. Gardner, who last week was appointed receiver for the Atlas Engine Works, of Indianapolis, Ind., has filed a petition in Judge Weir's room of the Superior Court, asking permission to sell the property and holdings of the company. In the petition Gardner sets forth that the indebtedness of the company approximates $1,000,000 and that in his opinion it will be impossible to obtain sufficient money to continue the plant in operation, and that if it were shut down considerable loss would result. The argument will be heard today.

Veerac Seeking Site in California.

According to reports from the Pacific Coast, the Veerac Motor Co., of Anoka, Minn., is seeking a factory site in Richmond, Cal. It is stated that negotiations are being carried on with a Richmond real estate firm and have for their purpose the establishment of a large truck factory on the coast.

Henry Ford Sails to Europe Saturday.

Henry Ford, president of the Ford Motor Co., of Detroit, Mich., will sail to Europe on Saturday, 13th inst., where he will remain several weeks. While Ford's visit will be largely in the pursuit of pleasure, it is certain that his commercial eye will remain wide open.

COURT DEFINES "SATISFACTION"

Says it's a "Mental Process" in Discussing a "Satisfaction Contract"—Then Reverses Decision of Lower Court.

When the Circuit Court of Wayne County, Michigan, Judge James O. Murfin, sitting, reversed the decision of the lower court and ordered a new trial in the case of Isbell vs. Anderson Carriage Co., William G. Isbell, the plaintiff, having received a verdict of $23,476 damages for alleged breach of contract, much light was shed on the meaning of the phrase "satisfaction contract," and, incidentally, a concise definition of the word "satisfaction" was given, this state being, in the words of the learned Michigan justice, "primarily but a mental process." The action in which the original verdict was handed down was instituted by Wm. G. Isbell against the Anderson Carriage Co. and was to recover damages for alleged breach, by wrongful termination, of a contract giving the plaintiff and one George D. Grant the agency for the sale of Anderson electric automobiles during a period of five years.

At the time of entering into the contract, Isbell and Grant were associated as partners and agreed by the terms of the contract to "establish the Anderson Electric Agency for the exclusive sale of the cars and electric automobiles that are made by the Anderson Carriage Co.," which at that time (1907) just had placed its vehicles on the market, though only one of them had been disposed of. The principal bone of contention was a phrase in the contract to the effect that the manner of conducting the agency was to be "such as will at all times be satisfactory to the Anderson Carriage Co.," and it was over the cancellation of the contract for alleged dissatisfaction after about 5½ months' duration that the action was commenced.

It was about three months after the contract had been put in force that trouble manifested itself, the Anderson Carriage Co. serving written notice on Isbell to the effect that the contract was not being carried out in a satisfactory manner. There were 12 itemized particulars in which it was claimed satisfaction was not forthcoming; they ranged all the way from "lack of advertising in the daily papers" and failure to employ competent help to a business policy which was not such as "to foster the sale and use of Anderson electrics in the city of Detroit." In the same communication it was intimated that unless these matters were corrected within 60 days, as prescribed in the contract, the Anderson Carriage Co. would consider the contract canceled. In replying, Isbell and Grant vigorously denied that the particulars named in the notice were borne out by the facts or that they had failed to observe their contract. Nevertheless, on March 2d, following, the An-

Digitized by Google

derson Carriage Co. sent them written notice that, owing to their failure to carry out the conditions of the contract "the same is hereby canceled."

During the continuance of the trial, amendments to the plaintiff's declaration were filed and a third count added. In it it was averred that the defendant "was not at any time in good faith and honestly dissatisfied with any of the actings or doings of the said Isbell and Grant . . . and that the defendant had repeatedly expressed satisfaction therewith, but that on March 2d, 1908, with fraudulent, surreptitious and ulterior design to cancel the said contract and to be freed of the duties and obligations therein imposed upon the said defendant, and to unlawfully and fraudulently make other arrangements in relation to the sale of its said cars, which did on said date cancel said contract."

It was on this amendment that the issue was taken and on which the case virtually hinged. In rendering decision, the court said in reference to it:

"The issue was raised in this case by plaintiff's amended declaration. To maintain it plaintiff introduced evidence of repeated expressions of approval and satisfaction, by Anderson, as to what was done and the general method of conducting the business, up to the time the notice of December 31 was served and of refusal to confer or co-operate thereafter; of dealings by defendant with others which resulted in a contract giving them the agency on better terms for defendant, before the sixty days specified in the contract and notice had expired. While the provision found in the supplemental contract, that sixty days' notice shall be given to correct any error or mistake that may arise in carrying out the conditions outlined in paragraph number two of said contract, is somewhat obscure and does little to illuminate the doubtful portions of the paragraph referred to, it does make plain that when dissatisfaction first arises another chance will be given, during a period of sixty days, to make things satisfactory before a final decision is reached. Good faith and an honest compliance with this require that, during the sixty days, defendant shall reserve judgment, remain in a receptive mood and be ready and willing to co-operate and approve, if possible, to the end that the contract may continue if the causes of dissatisfaction shall be in truth removed."

The case at issue was a delicate one for the jury to decide, inasmuch as it had to determine whether or not the defendant actually was dissatisfied. In other words, it was necessary to ascertain exactly what constitutes satisfaction. In the lengthy decision that was handed down and in which there were many precedents quoted, the court summed up as follows, and, as already has been told, reversed the original decision and ordered a new trial:

"Contracts of this general character, known as 'satisfaction contracts,' in which one party agrees to perform his part to the satisfaction of the opposite party, are fruitful and frequent sources of litigation, owing to the disappointments they so often bring to the party who has taken the chance of performing satisfactorily, and the difficulty of ascertaining what really constitutes satisfaction, which, primarily, is but a mental process. Such contracts are enforcible, however, to the extent the intention of the contracting parties can be ascertained. If parties voluntarily assume the obligations and hazards of a satisfaction contract, their legal rights are to be determined and adjudicated according to its provisions. It is elementary that courts cannot make contracts for parties nor relieve them of the consequences of their contracts, however ill-advised.

"In many cases of this nature which have been before various tribunals, there is recognized two quite well-defined classes; one where the personal taste, feeling, sensibility, fancy or individual judgment of the party to be satisfied are especially involved, the other where mechanical utility or operative fitness in relation to which some standard is available, are bargained for. In the former class the authorities preclude disputing the propriety or reasonableness of the declaration of dissatisfaction on the part of the individual entitled to exercise it. It is said to be with him purely a personal matter of which he is made the sole judge. It being his right to say whether he is satisfied or not it cannot be left to another to say that he ought to be satisfied. In the latter class of cases the authorities are more conflicting. In numerous decisions it has been held, under the phraseology of the contracts being considered and the attending circumstances, that not only the honesty of the declared dissatisfaction may be questioned, but even in special instances, the adequacy and reasonableness of the ground for such action are open to investigation.

"We think the contract under consideration falls more closely within the former class. It was an agency in the nature of employment to render services involving something more than the operative fitness or mechanical utility of a tangible thing. It involved personal efficiency, energy, initiative, business experience and ability to formulate methods and make them successful, as well as co-operation and confidential relations with defendant, of such a character as to lead to the conclusion that the parties contemplated, and provided for, the right of defendant to terminate the relationship when, according to its own fancy and judgment, the work done and methods pursued were not satisfactory."

Peerless Branch Replaces Agency.

Deeming the time auspicious, the Peerless Motor Car Co. has taken over the business of the Automobile Sales Corporation, which handled the Peerless in Philadelphia, and hereafter will conduct it as a branch, which temporarily will be located in the Abbott Building, at Broad and Race streets. Later it will be removed and permanently established at 245-247 North Broad street, where a handsome salesroom and service department are being made ready. R. W. Cook, former sales manager of the Automobile Sales Corporation, will be manager of the branch, and among his lieutenants will be George J. Dunham, at one time president of the Royal Tourist Motor Car Co., of Cleveland, O.

Three Months for Purloining Salesman.

Even if the Randall-Faichney Co., on Causeway street, Boston, Mass., makers of Jericho horns did not get much in recovery for 150 automobile horns which disappeared while one Arvid O. Swanson was in their employ as a salesman, the concern has the satisfaction of knowing that Swanson has three months in the House of Correction in which to meditate upon the advisability of depleting his employers' stock without their knowledge. The horns were alleged to have been taken by Swanson, a few at a time, but when the matter reached court last week the total valuation was placed at $500. Swanson gave Somerville, Mass., as his home.

Willys Enters Hexter Truck Company.

Growing out of the recent purchase by John N. Willys, of the Gramm Motor Truck Co., of Lima, O., Willys has been elected vice-president of the Hexter Motor Truck Co., of New York City, which company handles Gramm trucks in the metropolitan territory and in which the Gramm company holds a stock interest. Coincident with Willys's election, which occurred at a director's meeting, George W. Bennett, Willys's lieutenant, was made a director of the New York concern. As heretofore, P. K. Hexter remains president and general manager and Arthur A. Alexander continues secretary and treasurer.

Collapse of Garage Causes $50,000 Suit.

A somewhat unusual cause of action is named in Circuit Court by the A. J. Davies Motor Co. of Kansas City, Mo., which asks $50,000 damages from George W. and Dallas M. Tourtellots because a building at 1708-10 Grand avenue, owned by the Tourtellots and occupied by the Davies company, collapsed in March last. The complainants state that they had $75,000 worth of cars in the structure and that when it came crashing down upon the brightly painted vehicles they were left in somewhat undesirable condition.

Iowa Tire Filler in Bankruptcy Court.

On Saturday last, 6th inst., William A. Daugherty filed a petition in bankruptcy against the Iowa Tire Filler Co., doing business at 1324 Michigan avenue, Chicago. The liabilities of the company exceed $1,000; its assets are not a matter of record. The company was organized under the laws of South Dakota during the latter part of 1911 with $35,000 capital stock, which later was raised to $50,000.

Digitized by Google

THE WEEK'S INCORPORATIONS

Detroit, Mich.—General Castings Co., under Michigan laws, with $2,000 capital; to operate a foundry.

Detroit, Mich.—Power Truck Co., under Michigan laws, with $2,500 capital; to manufacture motor trucks.

Montpelier, Vt.—Union Transfer Co., under Vermont laws, with $2,500 capital; to operate a motor delivery.

Indianapolis, Ind.—Scheidel-Thompson Co., a Michigan corporation with $50,000 capital, admitted to do business in Indiana.

Franklin, N. H.—Herbert Mfg. Co., under New Hampshire laws, with $10,000 capital; to manufacture piston rings and other motor parts.

Minonk, Ill.—Minonk Garage Co., under Illinois laws, with $2,500 capital; to operate a garage. Corporators—D. L. Stimpert, I. R. Stimpert, R. E. Gray.

San Antonio, Tex.—Ford Sales Co., under Texas laws, with $5,000 capital; to deal in motor cars. Corporators—M. D. George, Clifton George, G. H. King.

Corinth, Miss.—Corinth Auto Co., under Mississippi laws, with $10,000 capital; to deal in motor cars. Corporators—W. A. Stewart, H. A. Hinton and others.

Detroit, Mich.—Parker Avenue Garage Co., under Michigan laws, with $10,000 capital; to operate a garage. Corporators—Herman F. P. Parker and others.

Flatonia, Tex.—Flatonia Automobile Co., under Texas laws, with $5,000 capital; to deal in motor cars. Corporators—E. A. Arnim, Donald McKay, C. P. Johnson.

Chicago, Ill.—Seek Auto Co., under Illinois laws, with $8,000 capital; to deal in motor cars. Corporators—James H. Seek, Herbert W. Crane, Emmet W. Mick.

Rye, N. Y.—Jacob Werner, Inc., under New York laws, with $1,000 capital; to deal in motor cars. Corporators—Jacob Werner, Ellen J. Werner, George J. Werner.

Camden, N. J.—Auto Distributers, Ltd., under New Jersey laws, with $200,000 capital; to deal in motor cars. Corporators—F. H. Hansell, I. C. Clow, J. A. MacPeak.

Far Rockaway, N. Y.—New Garage Co., under New York laws, with $1,000 capital; to operate a garage. Corporators—John A. Kilgallon, Michael J. Walsh, John J. Walsh.

Sidney, Ohio—Alumalux Co., under Ohio laws, with $5,000 capital; to manufacture solder, etc. Corporators—J. Henney, Robert E. Pfeiffer, Louis McAllister and others.

Camden, N. J.—International Motor Co., a Delaware corporation with $10,000,000 capital, admitted to do business in New Jersey with a principal office in Jersey City.

Weyauwega, Wis.—Weyauwega Garage Co., under Wisconsin laws, with $5,000 capital; to operate a garage. Corporators—E. H. Jones, F. W. Bauer, Claude Hinchey.

Syracuse, N. Y.—Jefferson Garage Co., under New York laws, with $30,000 capital; to operate a garage. Corporators—Antonia Matzene, Charles J. Roehm, Charles J. Baumer.

Wilmington, Del.—Rutenber Motor Co., under Delaware laws, with $1,350,000 capital; to manufacture motors. Corporators—Norman P. Coffin, W. Maloney, Herbert E. Latte.

Dover, Del.—Auto Signal and Mfg. Co., under Delaware laws, with $100,000 capital; to manufacture motor car devices. Corporators—H. H. Nobel, E. G. Ott, T. H. Humphry.

Buffalo, N. Y.—L. G. Schoepflin Co., under New York laws, with $10,000 capital; to deal in motor cars. Corporators—Louis G. Schoepflin, L. O. Schoepflin, Herbert G. Schoepflin.

Chicago, Ill.—Chicago General Motor Bus Co., under Illinois laws, with $1,000 capital; to operate a 'bus line. Corporators—Henry W. Berg, W. C. Norton, John Reckinger.

Rochester, N. Y.—Shafer-Decker Co., under New York laws, with $50,000 capital; to deal in motor cars. Corporators—C. P. Huge Schoellkopf, Charles P. Shafer, Frederich Decker.

Dover, Del.—Auto Development Co., under Delaware laws, with $500,000 capital; to manufacture motor car devices. Corporators—F. R. Hansell, G. H. B. Martin, S. C. Seymour.

Syracuse, N. Y.—New York Motors, Inc., under New York laws, with $10,000 capital; to manufacture motors. Corporators—Ernest W. Lawton, Theodore Young, Charles S. Lawton.

Elmira, N. Y.—International Resilio Co., under New York laws, with $50,000 capital; to manufacture tire fillers. Corporators—P. E. Lonagan, H. B. Collin, S. L. Welch, D. L. Thorpe, R. F. Nichols.

Fort Worth, Tex.—Cartercar Sales Agency of Texas, under Texas laws, with $10,000 capital; to deal in motor cars. Corporators—B. C. Rhome, Jr., Tom Frazier, W. B. King, O. W. Mathews.

Portland, Me.—Edwards Motor Car Co., under Maine laws, with $2,000,000 capital; to manufacture motor vehicles. Corporators—Clarence E. Eaton, T. L. Croteau, Albert F. Jones, B. M. Maxwell.

Gainsville, Fla.—Kelley Self-Starter Co., under Florida laws, with $200,000 capital; to manufacture motor starters. Corporators—W. R. Thomas, M. H. DePass, P. Miller, G. Hartwell Kelley and others.

Marion, Ind.—Railway Motor Car Co., under Indiana laws, with $200,000 capital; to manufacture motor cars. Corporators—W. O. Worth, J. D. Worth, Hiram Benhore, G. R. Stewart, Eben H. Wolcott.

Wilmington, Del.—Standard Auto Coach Burial Co., under Delaware laws, with$ 500,000 capital; to manufacture motor vehicles. Corporators—I. Neuberger, F. C. Cothran, S. Lewenstein, W. Litzenberg, C. H. Tebbetts.

New York, N. Y.—East End Garage Co., under New York laws, with $1,000 capital; to operate a garage. Corporators—Henry Krauss and Pauline Krauss, both of 24 Avenue D, and Max Steindler, 122 Columbia street.

Glenn Springs, S. C.—Smith Automobile Transfer Co., under South Carolina laws, with $700 capital; to operate an automobile 'bus line and delivery. Corporators—Clement F. Smith, Paul Simpson and others.

West Falls, N. Y.—Golden and Buffalo Auto Service Co., under New York laws, with $2,000 capital; to operate an automobile 'bus line. Corporators—Fred Hay and S. Hay, both of West Falls, and Conrad Leupold, of Buffalo.

New York, N. Y.—Russian Tyre Sales Co., under New York laws, with $30,000 capital; to deal in tires. Corporators—Otto Braunworth, 601 West 162d street; H. Ray Paige and Maud Steinway Paige, both of 340 West 107th street.

Brooklyn, N. Y.—Dunham Auto Co., under New York laws, with $15,000 capital; to deal in motor vehicles. Corporators—Frank Dunham, 296 Sterling Place; Louis Carmadella, 656 Union street; Charles A. Apfel, 6818 Tenth avenue.

New York, N. Y.—Canadian Overman Co., under New York laws, with $50,000 capital; to deal in tires, etc. Corporators—W. Albert Pease, Jr., 340 Madison avenue; Albert Z. Gray and Lusius Wilmerding, both of 5 Nassau street.

New York, N. Y.—Universal Auto Supply Co., under New York laws, with $10,000 capital; to deal in motor accessories. Corporators—George F. Connolley, 3505 Broadway; John J. Treacy, 3 West 63d street; John R. Hunt, 867 39th street.

MEN WHO HAVE SHIFTED POSITIONS

Resignations and Promotions That Served to Place Many Workers in New Places —Few Leave the Trade.

W. H. Radford, designing engineer for the Warren Motor Car Co. of Detroit, has been promoted to the post of factory manager. W. H. Knowles succeeds him as head of the Warren engineering department.

H. W. Evans, who for the past two years has been connected with the Locomobile branch in San Francisco, has been placed in charge of the Locomobile's truck business on the Pacific Coast. He will remain attached to the San Francisco branch.

J. P. Griffin, formerly with the Merchant & Evans Co. of Philadelphia, has joined the sales staff of the Enterprise Metal Co. of Syracuse, N. Y., and will cover New York State. The company is well known to the trade because of its Vanadium bearing metal.

Charles E. Wertman, who previously had charge of the sales department of the Matheson Automobile Co. in Wilkes-Barre, Pa., has been promoted to the management of the Matheson branch, New York. He succeeds G. H. Duck, who recently joined the Alco staff.

L. D. Sullivan, previously connected with the Crocker-Wheeler Co. of Ampere, N. J., has assumed charge of the experimental department of the E. B. Van Wagner Co., of Syracuse, N. Y. The company just has completed an addition to its factory, which provides much more room than was previously available for experiments and tests of its die castings.

Ford Hawes, for ten years chief engineer of the Cadillac Motor Co. of Detroit, and a figure in the General Motors affairs, has joined the Flanders Mfg. Co. of Pontiac, Mich., in the capacity of detail engineer. He is the second of the General Motors staff to join the Flanders staff, C. A. McGee, controller of the General Motors Co., having preceded him.

M. A. Weissenburger, who for the past 18 months has covered the New England States and the territory adjacent to New York City for the Regal Motor Car Co., has been transferred to Regal service on the Pacific Coast. He will take over some of the duties performed by Bert S. Bingham, who recently resigned as the Regal's Pacific Coast manager.

George A. Crane has been appointed the manager of the Chicago Truck Department of the Locomobile Co. of America, with headquarters, of course, at the Chicago branch. Crane has been identified in the industry for some eight years, just having served with the Knox Automobile Co. for a considerable term and later with the United States Motor Co.

W. E. Moore, who since its inception has been superintendent of production for the Nyberg Automobile Works of Anderson, Ind., has been promoted to the post of assistant general manager. Otto Schultz succeeds him as superintendent. Schultz has had experience with the Mercer and National companies, but latterly has been engaged as superintendent of the Falls Motor Co., of Sheboygan Falls, Wis.

Joseph E. Warren, who successively served with the Chalmers and Everitt, has been appointed district manager for the Pacific Coast for the Abbott Motor Car Co., of Detroit. He will make his headquarters in San Francisco. E. D. Hand, formerly assistant sales manager for the E. R. Thomas Co., also has been appointed Abbott district manager. He will have charge of Ohio, Pennsylvania and West Virginia.

Burt S. Bingham, Pacific Coast sales manager for the Regal Motor Car Co. of Detroit, has resigned that office to become manager of the Fresno branch of the Pioneer Automobile Co. of San Francisco, which distributes Chalmers and R. C. H. gas cars and Flanders electrics in northern California. Bingham succeeds A. C. Wheelock, who has been transferred to the Pioneer headquarters in San Francisco.

May Illuminate Klaxon-Newtone Situation.

Although several somewhat similar suits have been instituted by the Lovell-McConnell Mrfg. Co., for infringement of its Klaxon horn patents, it is probable that the first decision that will shed a strong light on the troubled situation will be rendered by Justice Brown in the Federal court in Providence, R. I. The Lovell-McConnell Mfg. Co. has asked for an injunction restraining the Waite Auto Supply Co., of Providence, from handling the Klaxon horn because of its alleged violation of the Klaxon conditional license, which violation consisted of the sale of Newtone horns, the Klaxon license requiring that dealers shall not handle infringing articles. When the case came up before Justice Brown, it was argued at considerable length and several phases not heretofore discussed were gone into.

Death Claims Studebaker's Old Manager.

George E. Keller, at one time general sales manager for the Studebaker Corporation, and one of the truly loyal members of the Studebaker staff, died last week at his home in South Bend, Ind. He had been ill for a long time, his illness becoming so acute that last September he was obliged to relinquish active work. He was 43 years of age and is survived by a widow and three children.

Kansas Spring Wheel to Change Base.

The Durgin Auto-Wheel Co. of Lawrence, Kans., has accepted a proposal to remove to Hutchinson, in the same state. The plant employs 15 men and produces a spring wheel invented by F. H. Durgin.

MAY LEAD TO WAR OF TAXIMETER

Owner of Jones and Popp Patents Forces Issue—Sues Taxicab Operators and Rival "Leasing" Company.

What is the first of a series of similar suits designed to enforce the lease of the taximeters used on most of the taxicabs in New York City has been instituted in the Supreme Court for New York County by the American Taximeter Co. of New York, of which Francois Ducasse is president. It is directed against not only John Hefferon and John Kavanagh, who operate as the Circle Taxicab Co., but against the International Taxameter Co. of America.

According to the complaint in the case, Hefferon and Kavanagh signed a lease to use only the Jones taximeter which, like the Popp taximeter, is owned and controlled by the American Taximeter Co., the terms of the lease requiring a deposit of $30.00 and the payment of a monthly rental fee of $6.00 for each taximeter, Hefferon and Kavanagh agreeing not to use a taximeter of any other make during the life of the contract. Before it expired, however, it is alleged that they substituted instruments made by the International Taxameter Co. Hence the suit, which charges that the International Taxameter Co., although well aware that Hefferon and Kavanagh were bound by contract to exclusively use for a period of three years either the Jones or Popp meter, induced them to violate the contract and to execute another lease which is substantially a duplicate of that used by the American Taximeter Co. The latter, therefore, asks that an injunction be issued restraining Hefferon and Kavanagh from using the International meter and that the International Taxameter Co. be enjoined from leasing or selling any taximeter to the other parties to the defense, and that it be required to account for the profits made by reason of its transaction with Hefferon and Kavanagh. "Such damages as are ascertainable" also are prayed for.

The original contract involved was made in November, 1909, with the Jones Taximeter Co., which on April 1, 1910, was purchased by the American Taximeter Co., the purchase carrying with it all contracts and the patent on the Jones taximeter, No. 951,077, dated March 1, 1910. The International company has American rights to a patent owned by a German company, but is patenting a taximeter of its own.

Motz Establishes Two More Branches.

The Motz Tire & Rubber Co., of Akron, O., has opened branches in both Philadelphia and Cleveland. The Philadelphia branch is located at 1409 Race street, and is in charge of William M. Stubbs, while Charles Serfass has been made manager of the Cleveland branch, which is located at 2352 Euclid avenue.

George Saindon has opened a garage in Zurich, Kan.

C. O. Stensend has opened a garage in San Diego, Cal.

Dr. W. P. Barnes has opened a garage in West Harwich, Mass.

Albin Bengston is erecting a garage on Main street, Luck, Wis.

Claude Huffman has opened a garage on Main street, Scranton, Ia.

The Everitt Motor Car Co. has opened in Tampa, Fla. Bruce Neff is manager.

Twisp, Wash., has a new garage; J. A. Eisley of that town is the proprietor.

Louis Schoetke and John Beemer are about to open a garage in Marengo, Ia.

J. G. Lawrence, of Wabash, Minn., is making ready to open a garage on Main street.

A. T. Schleismayer, of Long Beach, Cal., has opened a repair shop at 1108 Magnolia avenue.

A garage, 47 x 134 feet, is being built in Los Angeles, Cal., on Selma avenue, for E. L. Baker.

W. K. Van Wagoner, of Ida Grove, Ia., has remodeled his barn into a garage and automobile livery.

Under the style Dodge, Speiser & Porter a new Hupmobile agency has opened up in Durango, Cal.

F. L. Bristol, of Portsmouth, N. H., has opened a garage on C street, Hampton Beach, in the same state.

William Daniels, of Manistee, Mich., has leased the Airdrome in that city and will convert it into a garage.

Ray Neal, of Ashland, Ky., has entered the garage field; his place of business is at 17th and Market streets.

E. A. Nelson, an East Swazey (N. H.) mill owner, is erecting a garage near his present place of business.

J. W. Corkins, of Rockham, S. D., has purchased the Walter & Co. garage; he will continue the business.

William Steele and Walter McClellan have opened a garage in West, Tex. They will handle accessories, also.

F. B. Alexander, formerly of Little Rock, Ia., has engaged in the automobile trade in Sioux City, in the same state.

O. C. Lane is constructing a garage and machine shop in Burbank, Cal. The plans call for an expenditure of $10,000.

The McWilliams Auto Co., of Liberal, Kan., has filed a petition in bankruptcy. Assets are $1,500 and liabilities $2,000.

Jarold W. Sindell has sold the Dayton (O.) View Gymnasium to J. Glaser; the latter will transform it into a garage.

Charles C. Snodgrass, of Sisterville, W. Va., has purchased the Irwin Garage, in the Pennsylvania town of that name.

The Centralia (Wash.) Auto Garage Co. has been sold by the owners, Brunton Bros., to A. C. St. John, of Chehalis, Wash.

Rosco & Monteith is the style of a new garage firm in Ellendale, N. D. It is located at Second avenue and 3d street.

Work has been commenced on a garage on Newberry street, Newberry, Pa. It will be owned and operated by Funston Hill.

A garage, being erected at the rear of the Park Square Hotel, Springfield, Mass., by Samuel Squire, has been leased by R. D. Earle.

Harry Cohn, of Syracuse, N. Y., is about to erect a garage on McCarthy avenue; it will be two stories, 50 x 35 feet, and cost $5,500.

Joseph Ziegler, of Anderson, Ind., has accepted plans for a business block and garage to be erected at Meridian and 14th streets.

Andrea Steidel is about to erect a one-story brick garage, 42 x 102 feet, at 255 Bergen street, Newark, N. J. Its cost will be $7,000.

Under the style Auto Cleaning and Exchange Co., W. B. Hart and E. C. Shafer have opened a garage in West Lowe lane, Dayton, O.

Robert Doyle, of Nashua, N. H., has leased and will operate a garage at Old Orchard, Me.; it will be open only in the summer season.

The Cadillac Garage, in Fresno, Cal., which was recently destroyed by fire, is to be rebuilt immediately; the new structure will cost $11,000.

W. E. Burch, of Los Banos, Cal., is building a garage on 6th street; when completed it will be occupied by D. M. Rouse and J. W. Hulen.

Under the style Albert Lea Carriage & Automobile Works, Marinus Nielson and P. O. Nicolas have opened a garage in Albert Lea, Minn.

Robert Jensen has added his name to the list of garage operators in Whittier, Cal. His establishment is located at 309 West Philadelphia street.

Paul Utemark and Henry Wreidt, of Silver City, Ia., have formed a partnership and will erect a garage, 50 x 100 feet, in the central part of the town.

J. S. Moore, formerly of Chico, Cal., has removed to Red Bluffs, the same state, and will open a garage; he has secured the Ford agency for Tehama County.

Fred Van Sickle and W. J. Nichols are about to open an agency in Middletown, O. They will handle E-M-F, Studebaker, Flanders, Oakland and other cars.

Joseph Paquet has about completed a three-story garage at East 8th street and Hawthorne avenue, Portland, Ore. It represents an expenditure of $30,000.

John W. Williams has purchased the interest of A. W. Peterson in the firm of Chellin & Peterson, automobile dealers; the new style will be Chellin & Williams.

Madison, N. J., will soon be possessed of a new garage, 50 x 125 feet, located on King's road; Frederick W. Wilson, the owner, will expend $8,000 in its construction.

The garage in Fairbury, Neb., at 5th and F streets, operated by Berton Simmons, has been taken over by William Lewis; the men at one time were partners in the business.

A branch office of the Essenkay Co., of Chicago, tire filler manufacturers, is about to be opened at 715 Maiden lane, Fort Wayne, Ind. E. H. Kilbourne will be in charge.

Under the style McGinnis Auto Co., a Staver-Chicago agency has been opened in Lynn, Mass., at 65 Andrew street; the members are J. A. and J. B. McGinnis and E. L. Collins.

Morgan V. Disbrow is about to open a garage on Bridge avenue, Red Bank, N. J.

A garage has been opened in Bloomer, Wis., by Charles Keller, John Thornton and Peter Harring.

The Central Garage Co., of New Brunswick, N. J., has added to its business by leasing for five years the garage of W. J. McDede on Albany street; it will be conducted as a branch.

The Vollmer-Apgar Co., of Monroe, La., has purchased the stock and business of the Monroe Garage and Supply Co. The new concern will sell E-M-F, Flanders, Overland and other cars.

The White Bear Auto Co., of St. Paul, Minn., has absorbed the R. C. H. agency in that city; S. W. Wicks, manager of the R. C. H. agency, becomes sales manager for the White Bear company.

Cushing, Bros., of Campello, Mass., have secured permission to build a brick and concrete garage at East Chestnut and Montello streets; it will be 89 x 59 feet and will represent an expenditure of $10,000.

N. George Wahlberg and C. E. Johnston, formerly employes of the Thomas B. Jef-

Digitized by Google

fery Co., of Kenosha, Wis., have secured an interest in the Purdy Garage, on Church street, in that city; they have left the Jeffery company to "take up for themselves."

C. T. Muller, M. J. Wittson and J. Schall have opened up at 55 Warburton avenue, Yonkers, N. Y., as the Terrace City Sporting and Auto Goods Co. Muller formerly was connected with the Shrive Garage in Yonkers.

The Iowa Auto & Supply Co., of Des Moines, Ia., has taken over the business of the Ryan Motor Car Co., the Chalmers dealer; the Iowa concern also handles the Locomobile, National, Marion and Woods Electric cars.

George J. Kohles, of Earling, Ia., and J. H. Deen, of Harlan, in the same state, have opened a garage in the latter town; they will, besides conducting a repair business, handle the E-M-F and Flanders cars and maintain a livery.

Karl Kaus, of Hampton, Ia., has sold his garage and some adjoining real estate to the Colby Motor Co., of Mason City, in the same state; the purchasing concern will tear down the present structure and build a garage, 64 x 110 feet, which it will use as a branch.

Samuel H. Rosenthal, of Chicago, has purchased of John E. Kernett and Clarence E. Beck property at 2436-38 Michigan avenue and will erect thereon a two-story service building at a cost of $40,000; the Hupmobile agency will occupy the structure when completed.

R. M. Weaver, general manager of the Columbus (O.) Machine Co., and W. J. Miller, superintendent, have resigned to purchase the Broad-Oak Automobile Co., in the same city; the latter concern has the Chalmers and Pierce-Arrow agencies. Miller was at one time connected with the Frayer-Miller Automobile Mfg. Co.

Walter J. Bemb, former central district sales manager for the Hudson Motor Car Co., and L. J. Robinson, former Southern district sales manager of the same company, have formed the Bemb-Robinson Co., to handle the Hudson line in Detroit, Mich. The new firm succeeds the J. H. Brady Co. as Detroit representative of the Hudson company and will occupy the Brady headquarters at 288 Jefferson avenue.

Recent Losses by Fire.

Bangor, Me.—S. L. Crosby Co., garage and forty cars destroyed. Loss, $15,000.

Scranton, Pa.—Robert Lance, Decker Court, garage destroyed. Loss, unknown.

Montgomery, Ala.—Alabama Auto Co., Court Bibb and Tallapoosa street, garage destroyed. Loss, $10,000.

Atlanta, Ga.—Atlanta Baggage and Cab Co., 44-46 Madison avenue, garage and thirteen taxicabs and others cars damaged. Loss, $20,000.

REORGANIZING THE LONDON OMNIBUS

Speyer Interests Make Public Their Plans —New Capitalization Exceeds $21,000,000 —How Old Stockholders Will Profit.

According to present indications, the already immense London General Omnibus Co., which operates a fleet of some 600 'buses in the streets and environs of London, England, is about to still further increase its activities, ambitious plans, which call for a material increase in capitalization, having been but recently proposed. The "shake up," which in all probability will result in the formation of a new company of the same name, was forecast a few months ago when the so-called Speyer group, which controls all the underground electric railways in the city, acquired control also of the London General Omnibus Co., the proceeding taking the form of the transfer of securities of the Underground Electric Co. in exchange for omnibus stock, the Speyers thereby obtaining 94 per cent. of the Omnibus company's capital.

Under the new scheme, the new London General Omnibus Co. will be capitalized at $6,250,000 in ordinary shares of $50 each. There also will be issued the following debenture stocks: $6,500,000 in 4½ per cent. first mortgage stock and $8,750,000 in 5 per cent. income stock, making the total capitalization $21,250,000. In addition to ordinary old stock outstanding to the amount of $6,000,480, the present company has the following prior charges: $1,955,400 in preferred stock, $1,500,000 in 4 per cent. debentures, $750,000 in 5 per cent. "B" debentures (repayable at 110), and $1,020,250 in 5 per cent. "C" debentures, the total being $11,226,130.

Under the scheme of reorganization which has been proposed, holders of preference shares and of various classes of debentures are offered to be paid off in cash or to be reinstated in the new company by being given holdings equivalent to those they relinquish. In either case, the option of either 4½ per cent. first mortgage stock or 5 per cent. cumulative income stock being given, the stock selected is to be taken at the price of issue to the public. Holders of ordinary stock will receive a cash dividend of 10 per cent., payable out of accumulated profits, and the stock will be purchased from the liquidator at the rate of $1,375 per $500 of stock.

Goodyear's New York Branch Expands.

After a long term of years on the corner of Broadway and 64th street, the Goodyear Tire & Rubber Co. of New York just has moved into more commodious quarters in its own building, on Broadway, between 66th and 67th streets, New York City. The building, which only recently was completed, is five stories in height and affords a total floor space of 20,000 square feet. Henceforth the headquarters of the New York company will be in the new building, affairs, as heretofore, being under the active management of J. B. Maus. On the two-acre plot of ground which the company recently purchased in Long Island City, opposite the Ford service building, announcement of the purchase having been made some three weeks ago in the Motor World, the company immediately will erect a six-story warehouse building which will provide close to 100,000 square feet of floor surface for storage purposes. It is expected that the warehouse will be ready for occupancy about January 1st, 1913.

American Underslung Rearranges Staff.

C. E. Perrin, who for the last three years has been assistant sales manager of the Regal Motor Car Co., Detroit, has resigned that position to become sales manager of the American Motors Co., of Indianapolis, makers of the Underslung American. Perrin will relieve D. S. Menasco, vice-president of the company, of immediate direction of the sales department, as henceforth Menasco will devote himself to field work and spend the greater part of his time in keeping in personal touch with American dealers. D. B. Williams, who formerly combined the duties of assistant sales manager and advertising manager for the American company, also will relinquish direct connection with the sales department and hereafter will devote himself wholly to the advertising and publicity work of the company.

Asch Gives Weed Judgment by Default.

Because Benjamin M. Asch of New York City, an accessory dealer, failed to enter an answer to an action brought against him by the Weed Chain Tire Grip Co., asking that he be restrained from handling the "Best" grip, an alleged infringement of the Parsons patent, No. 723,299, a decree pro confesso was entered against him last week and likely will be made permanent. The grip in question is of the "anchored" type and is manufactured by H. E. McLain & Co., of Natick, Mass.

Carter Bell Not to Make Motor Tires.

In spite of published reports that the Carter Bell Mfg. Co., of New York, had completed a factory in West Springfield, N. J., and purposed engaging in the manufacture of rubber tires for the automobile trade, M. E. Chidester, treasurer of the company, states that it has no intention whatsoever of manufacturing automobile tires of any sort. It is engaged in the manufacture of chemical products, not automobile tires.

Ford Secures Site in San Francisco.

After a considerable period of negotiations, the Ford Motor Co. of Detroit finally has secured the site for its San Francisco assembling or service plant. It has purchased the entire block bounded by Harrison, 21st and 22d streets and Treat avenue.

Cable Address, "MOTORWORLD," NEW YORK.

Entered as second-class matter at the New York Post Office, November, 1900.

NEW YORK, JULY 11, 1912

ONE LAW THAT DESERVES A WELCOME.

On Tuesday next, the ordinance prohibiting the use of the muffler cut-out in New York City becomes effective. Whether it proves effective remains to be seen. Noting the pleasant anticipations of New Yorkers, a Detroit paper has served warning that it were well not to pitch hopes too high, for in Detroit a similar law is regarded as a joke and is more honored in the breach than in the observance.

In certain parts of New York, however, it is fair to predict that the law will be enforced, if not by the police, then by the sufferers themselves. For wherever there is located a garage or a grade, even though it be but one-half of one per cent, the suffering of the residents has been long, if not always patient. With a weapon within their reach, they are not likely to remain content to suffer a continuance of the aggravating nuisance due to the use of the muffler cut-out. There is no street noise which is more unnecessary or more irritating or more indefensible.

The too numerous man who finds it necessary to "increase his power" or to "cool his engine" by opening his muffler on the slightest incline, or who performs the same operation to "check the firing of his engine," or employs the cut-out in lieu of the horn for signaling purposes, or the man who frankly admits "he likes the noise"—all of them are common nuisances and should be treated accordingly. There are times and places for all things and the public street is no place for "cooling engines" and "testing" them in such fashion or otherwise making the motor car appear a nuisance which it is not.

Practically all explanations offered for the use of the cut-out are excuses, not explanations. It is to be hoped that when the prohibitary law becomes effective the courts of New York City will attach their real value to such explanations. The law is one that should be heartily welcomed by all considerate and right-thinking persons.

EXPLAINING THE PRICE OF GASOLENE.

In Great Britain, as in America, the soaring of the price of gasolene has set the automobile interests by the ears. There, as here, they have listened to stories concerning supply and demand and they have gone so far as to hold a meeting of protest, which, however, availed them nothing. The head of the British gasolene industry was present at the meeting and he was overfull of kind words and other pleasant conversation, worthy even of Standard Oil's own publicity bureau. Having made his gracious speech, the oil magnate returned to his stockholders and a few days later addressed to them another and a different speech. He congratulated them on the alleged fact that the price of gasolene had at last become "normal;" he said that too long it had been sold at unreasonably low prices and the inexorable law of supply and demand having at last exerted its effect, it was a great pleasure to announce the declaration of an extra dividend of 10 per cent and to prophesy that the financial returns for the year would constitute a record in the history of the company, which has been in the habit of declaring 20 per cent dividends annually, which is about the proportion of Standard Oil dividends.

It is not often that such speeches become public property, but when they do become public, nothing better serves to show, as too often is the case, that not supply and demand, but desire for dividends and "record years," is at the bottom of too many price advances. When 20 per cent dividends are possible on huge capitalizations, talk of supply and demand having affected the market from which such generously proportioned dividends spring is nine-tenths buncombe.

OIL DRIPPINGS AND WHAT THEY SIGNIFY.

Considerable discussion was indulged in at one time as to whether the oil and grease dropped by motor cars upon asphalt roadways was injurious to the asphalt; apparently this was decided in the negative, as the discussion has ceased while the dripping of oil continues.

But whether or not oil injures asphalt, there is no question that the loss of lubricants is injurious either to the cars or to the pockets of the owners. All the oil that escapes must be replaced, and some cars find it possible to lose a very considerable quantity of oil, as can be seen by a glance at the places where motor cars most do congregate. Moreover, where oil can escape, dirt and grit can work in—and it does so, to the detriment of the bearing surfaces involved.

The only way to prevent the escape of oil is to make all joints so snug that there is no likelihood of leakage. It is the duty of the manufacturer to see that the joints are properly made in the first place, and it is the business of the owner to see that they are kept in that condition. Catching oil in a pan and throwing it away through a drain plug is a half-way measure that serves only to cover up imperfect design or workmanship.

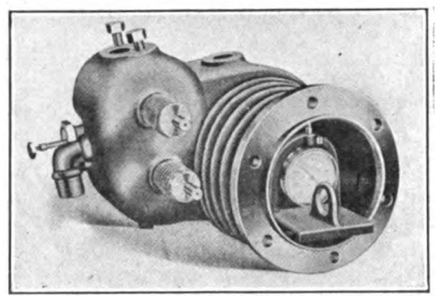
"DEVEROE" PROVES A GAY DECEIVER

Willingness to Work and Talk of "Factory Sales Manager" Enables Him to Victimize St. Louis—His Clever Scheme.

As plentiful as have been the methods of swindling that have been practiced on persons connected with the automobile industry, or attempted, it has remained for an enterprising individual who poses under the name "Deveroe" and who so far as can be learned has confined his operations to St. Louis, to evolve a brand new scheme which for plausibility and genuine art in consummation rarely has been surpassed. In addition to being a plausible talker, "Deveroe" —"Jay" is the first name under which he chooses to be known — appears to be a clever actor. It was the combination of these two qualities, and a penchant for real work, even if for short periods, and a certain facility in the use of shop tools that allayed suspicion and permitted him to carry on his nefarious trade to the annoyance and monetary cost of at least one well-known St. Louis sales agency.

Reduced to simple terms, "Deveroe's" modus operandi was delightfully simple. On Saturday, June 22d, he introduced himself at the St. Louis salesroom as a "road service man" from one of the New England automobile factories. In accounting for his appearance he explained that the factory sales manager had left him in Indianapolis with instructions to meet him in St. Louis. He relied upon his "knowledge" of his sales manager's movements to forestall any demand for credentials, and, to revert to the vernacular, he "got away with it."



He became a zealous mechanic and apparently had the training to work upon cars after the manner of real road corps men. For three days he put in his time industriously, but on Monday he appeared to be worried over the non-appearance of his sales manager and produced what purported to be a telegram from him stating that he had been delayed and would not reach St. Louis until the following Thursday, but instructing "Deveroe" to remain in St. Louis until he arrived. Soon other things commenced to bother him. He claimed he had not received his expense check and induced the St. Louis bookkeeper to cash a personal check for $35. He also felt that he should send some money home, and in view of the fact that he had "about $150 coming to him for salary and expenses, which the sales manager would O. K.," he presented a check the following day for $50.

Both checks were drawn on a bank in the city in which "Deveroe" claimed the factory which employed him is located, an illustration of his resourcefulness in making lies appear authentic. Telegraphic communication, however, brought word that the checks were fraudulent, but before this information reached St. Louis the "road service man" had taken the quickest road out of town.

Warning was wired to other companies and dealers, urging them to be on the lookout in case "Deveroe" attempted to resume business elsewhere. It has been impossible to identify "Deveroe" from a description, but it is believed that he is a man who was dismissed from some factory or that he has been employed elsewhere in a capacity permitting him to make a close study of persons and methods in its sales organization.

Cylinder Gauge of Great Accuracy.

By way of alleviating the troubles of "final inspectors" and materially increasing efficiency and the quality of workmanship, there recently has been perfected in England by George H. Alexander, of Doe street, Birmingham, a new type of cylinder gauge, which, it is claimed, will permit of the accurate gauging of cylinders to within one-quarter thousandth part of a millimeter. Though the gauge has been developed primarily for determining the accuracy of cylinder bores, its use, it is pointed out, is not confined to this purpose. The gauge may be used also for discovering inaccuracies in straight milled or planed surfaces, the method of application for such uses being apparent in the accompanying illustration, which shows the gauge in use in a cylinder casting.

ALEXANDER'S CYLINDER GAUGE

Because the gauge is controlled by a spring, the tension of which remains practically constant for long periods, and no dependence is placed upon the operator's sense of touch, as is the case with other methods of testing, it is claimed that the gauge is the most accurate instrument of the kind extant. In using the device, it is recommended that a standard ring of the absolute size of the finished cylinder bore be used in setting the dial, after which it is merely necessary to slip the gauge into the cylinders, inaccuracies showing plainly by the movement of the dial hand. As the dial may be graduated either to .001 mm. or .01 mm., the exact amount that any portion of the bore is "out" may be determined easily and correction in the grinding process made to overcome the inaccuracy. The gauge is regularly supplied in two sizes, the size illustrated being applicable to cylinders larger than 3½ inches bore by the use of points of different lengths. A smaller gauge for three-inch cylinders is the alternate size, though it is recommended that wherever possible the larger size be used, as it permits of the greater accuracy.

July 9-29, Indianapolis, Ind.—Annual Four States tour of the Indiana Automobile Manufacturers' Association.

July 13, Forestville, N. Y.—Hill climb under the auspices of the Forestville Motor Club.

July 15-16, Cleveland, Ohio—Reliability run under the auspices of the Cleveland News.

July 15-20, Milwaukee, Wis.—Reliability tour, under the auspices of the Wisconsin State Automobile Association.

July 21, St. Louis, Mo.—Track races under the auspices of the Universal Exposition Co.

July 22-28, Dallas, Texas—Farm and Ranch Tour under the auspices of the Dallas Automobile Club.

August 8-10, Galveston, Tex.—Beach races under the auspices of the Galveston Automobile Club.

September 2-3, Indianapolis, Ind.—Races on the Motor Speedway, promoted by the Indianapolis Motor Speedway Co.

September 7, Hadine, Minn.—Track races promoted by the Minnesota State Fair Association.

September 17, Milwaukee, Wis.—Grand Prize road race under the auspices of the Milwaukee Automobile Dealers' Association.

September 21, Milwaukee, Wis.—Vanderbilt Cup race on the Greenfield course, under the auspices of the Milwaukee Automobile Dealers' Association.

Three Judgments for Failure to Pay.

Because it neglected to meet obligations, two judgments were recorded this week in the New York County Clerk's office against the City Motor Car Co., of New Rochelle, N. Y., one for $300.75 being credited to the Swinehart Tire & Rubber Co. and the other, for $88.12, to the Endurance Tire & Rubber Co., both of New York City. One by F. Ray and others, trading as Smith-Haines, automobile supply dealers at 1761 Broadway, against the Central Tire Supply Co., of New York City, for $37.38.

U. S. Tire Breaks Ground in Boston.

Ground has been broken at the junction of Commonwealth avenue and Beacon street for an imposing five-story structure which, when completed, will be occupied by the Boston branch of the United States Tire Co. It will be ready for occupancy about January 1st next.

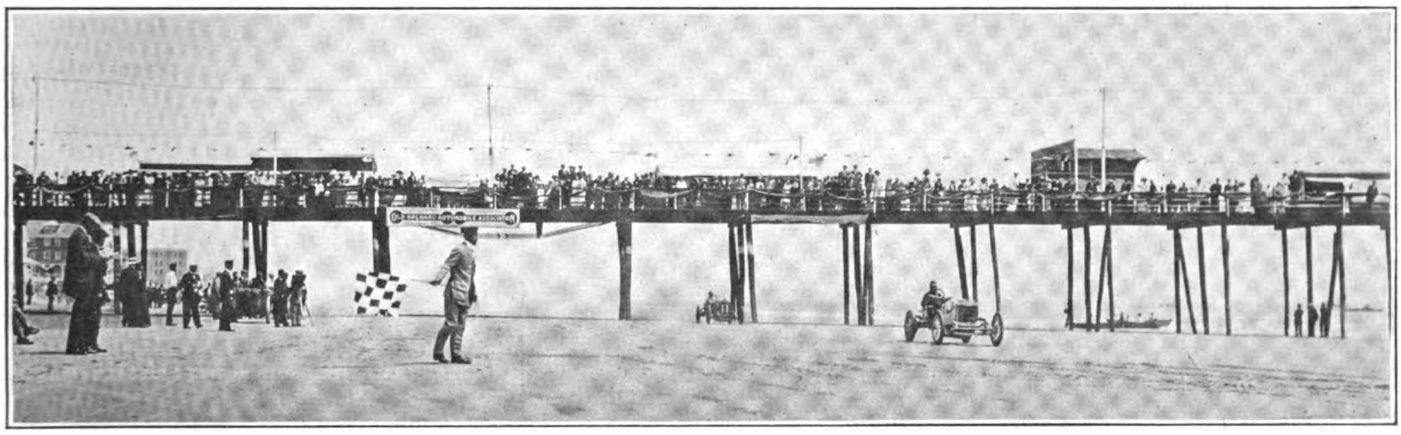
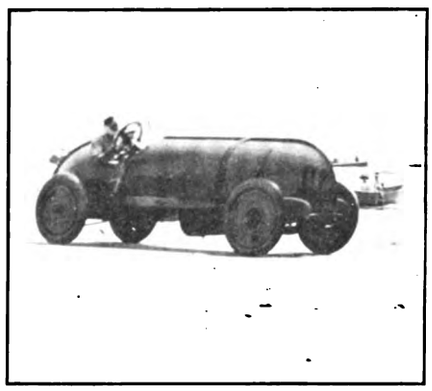
FINE SPORT ON OLD ORCHARD SANDS



But Scarcity of Spectators Chills Promoters —Honors Well Distributed—One Hundred-Mile Races the Feature Events.

Three days of fine weather and fine racing did not serve to make the Old Orchard speed carnival an undiluted success. Despite the weather and the racing, on two of the three days the crowd refused to attend; on the other day, July 4th, the crowd was big enough and interested enough to warm the cockels of the hearts of members of the Old Orchard Automobile Association, but the empty grandstand and the general absence of spectators on the 5th and 6th were sufficient to chill the heartstrings and marrow of the promoters. It was their second attempt, and unless they are possessed of unwonted courage and financial support, they are not likely to repeat the carnival another year.



Old Orchard, which probably is so called because there are no orchards within easy sight, forms part of the serrated coast line of Maine. It is more or less of a summer resort, which implies that it is possessed of a beach, but until last year the beach was not sung in automobile stories. It bears small resemblance to the famous strand of Florida on which automobile records of a cyclonic nature were set up, and the wonder is that it rendered possible such speed as was created during the three days of last week. This time it was real speed, too. For as those who have even fairly retentive memories will recall, they knocked automobile records sky high and galley west when the automobile carnival was inaugurated last year—that is, the records appeared to have been dispersed in the several directions until it was discovered that the Old Orchard course was a mere matter of two miles short in every five. They surveyed the course for last week's contest, however, and as electrical timing also prevailed, the figures probably will pass without dispute of any kind.

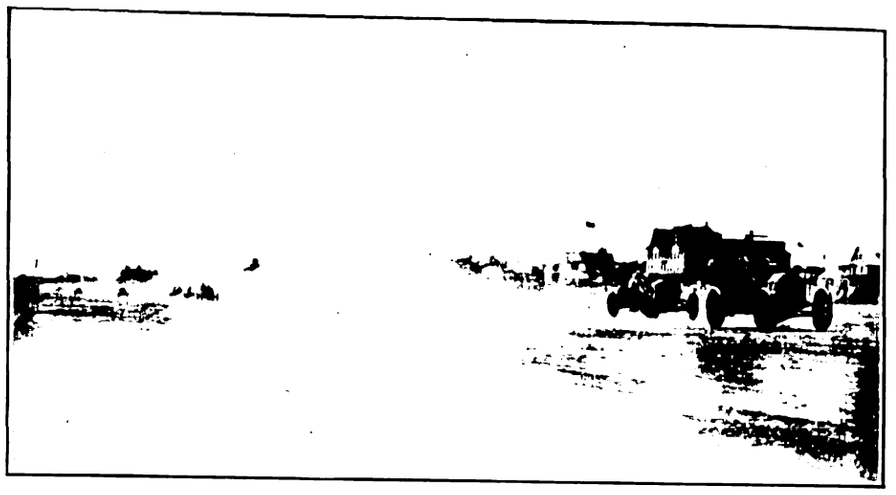
The course was two and a half miles out and home, a circuit of five miles, the turn being made around a barrel; and it was there that the sand flew in all directions, for the surface of the beach was neither so hard nor so smooth as might be; but despite the fact, some fast work was accomplished. No part of the record table was upset, but a full line of Old Orchard Beach records were set up to the great glory of Old Orchard and the Maine coast generally.

During the three days 18 events were decided, the most notable of which were the 100 mile races, one of which was scheduled for each afternoon. The one on the first day exemplified the fact that time and tide wait for no man, not even automobile racing men, for before more than three-quarters of the century had been traversed by the leader, Dave Lewis in a Stutz, the domain of Father Neptune had so far encroached upon the erstwhile race course that a halt was necessary. The race went for only 75 miles, Lewis's time for the distance being 1:17:48¾, while the time of Harry Grant (Berkshire) and Neil Whalen, who piloted a National, both of whom completed 65 miles before the course turned "wet," was 1:21:06 and 1:21:12, respectively. On the second day, however, due primarily to the expedition with which the rest of the program was carried out, the century grind was finished long before the rising tide covered the course, and finished, too, at a better than a mile-a-minute pace by William Endicott, who drove his Schacht over the finishing tape in 1:36:41. The real glory of the contest, however, belongs to Jack Rutherford, who finished in his National just nine seconds later than the winner, for it was he who had been pacemaker throughout 99¼ miles of the grind, and it was due to the breaking of a connecting rod as he was approaching the finish that he "lost out." He skipped across the line on three cylinders, however, finishing well over three minutes ahead of his team mate, Whalen, who took third position. The 100-mile race which was run on Saturday proved a "hurrah" for David Lewis, who drove his Stutz over the prescribed distance in 1:32:43⅘, very nearly four minutes better than the time made by Endicott on the day previous.

CLOSEST FINISH OF THE MEET—NIKRENT (CASE) BEATING JOHN DE PALMA (MERCER) IN 10-MILE EVENT ON JULY 4

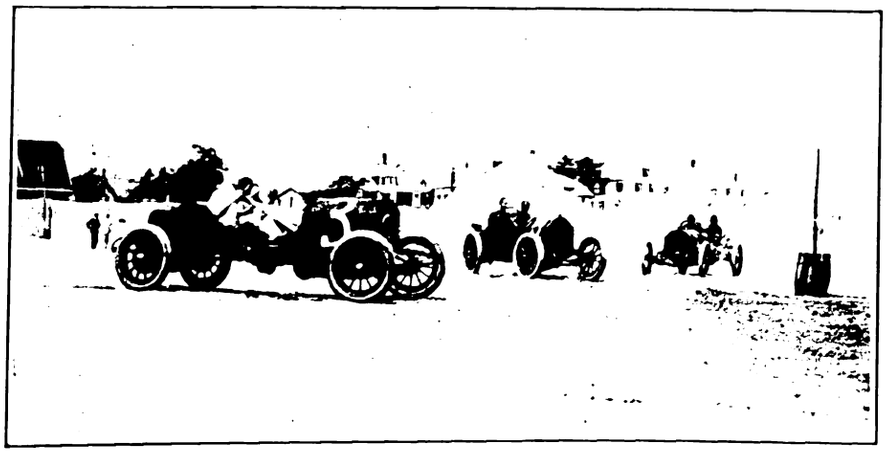
DISBROW AND THE "JAY-EYE-SEE"

Endicott, who took second honors, beat his time of the day previous by 32 seconds, crossing the tape over 14 minutes ahead of Harry Cobe, the Jackson driver, who finished third.



The best time of the carnival was made on the first day, when Louis Disbrow drove the reconstructed racing car "Jay-Eye-See" for a mile in 35⅕ seconds, at a rate of 102.3 miles an hour. Disbrow also took a ten-mile Class E event which was run on the first day, driving a Simplex across the tape in 8:36¾, nearly 14 seconds better than the time made by Joe Matron in the Fiat, who finished second. Two Class C events, for cars of 231-300 and 301-450 inches and which went for ten and for five miles, respectively, were taken by Joe Nikrent (Case) in 10:28⅗, and Harry Grant, who piloted the Berkshire, in 4:25¾, in the order named.

The honors of the second day were well divided. Disbrow took a five-mile free-for-all, again driving the Simplex, his time for the distance being 4:39 1/10; Dave Lewis (Stutz) finished 9-10 of a second later. Albert Hummel, who took turns driving a Mercer with John De Palma, a "debutante" brother of Ralph, cleaned up a Class E event for cars with displacements under 301 inches and which went for fifty miles. Hummel's time was 54:10½. William Burke drove his E-M-F entry to victory in a Class E event for cars with displacements under 301 inches and finished in 5:49. A Class C



Digitized by Google

event for cars with displacements of 301-450 inches, which went for five miles and was won by Jack Rutherford in the National, completed Friday's program.

Disbrow made two individual time trials on the last day of the carnival, driving the Jay-Eye-See, but neither in the five-mile trial, which was run in 4:04½, nor in the single mile, which he completed in :39 1/10, were the records endangered. Driving the Simplex, he also captured a ten-mile free-for-all in 8:53. Basle, in the Bianchi car, was second, his time being 9:32 1/10. A Class E event which was run in two sections, for cars with displacements of 161-230 and 231-300 inches, and which went for 25 miles, proved a hollow victory for William Burke (E-M-F), who ran in the smaller car division and completed the course in 27:10⅘. The division for the larger cars, however, was more hotly contested, and was won in 25:29 1/10 by Joe Nikrent in the Case. Nikrent also won the Class C event for cars with displacements of 231-300 inches, completing the ten miles in 9:54.

MATSON (FIAT) LEADING WHALEN (NATIONAL) IN FIRST 100-MILE EVENT

AT CLOSE QUARTERS ROUNDING THE BARREL

John De Palma (Mercer) finished five seconds later. The summary:

Thursday, July 4th.

One mile, time trials—Won by Louis Disbrow (Jay-Eye-See), time :35⅕; second, Jack Rutherford (National), time :47.

Ten miles, for cars with displacements of 231-300 inches—Won by Joe Nikrent (Case), time 10:28⅗; second, Alfred Hummel (Mercer), time 10:30¾.

Five miles, for cars with displacements of 301-450 inches—Won by Harry Grant (Berkshire), time 4:25 8-10; second, Dave Lewis (Stutz), time 4:42 1-10.

Ten miles, for cars with displacements under 600 inches—Won by Louis Disbrow (Simplex), time 8:36¾; second, Joe Matson (Fiat), time 8:50 1-10.

100 miles, Class E, run in three divisions, for cars of 301-450, 451-600 and over 600 inches—Called when Dave Lewis (Stutz) had completed 75 miles, time 1:17:48¾; Harry Grant (Berkshire), 65 miles, time 1:21:06; Neil Whalen (National), 65 miles, time 1:21:12.

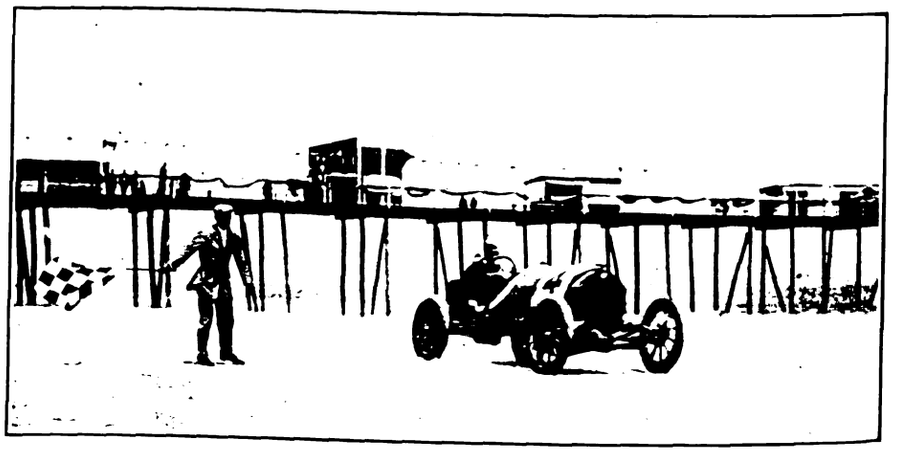
Friday, July 5th.

Five miles, free-for-all—Won by Louis Disbrow (Simplex), time 4:39 1-10; second, Dave Lewis (Stutz), time 4:40; third, Joe Matson (Fiat), time 4:42; fourth, Neil Whalen (National), time 4:50.

Fifty miles, cars with displacements under 301 inches—Won by Albert Hummel (Mercer), time 54:10½; second, Joe Nikrent (Case), time 55:45; third, Plimpton (S. P. O.), time 67:10¾.

Five miles, for cars with displacements under 301 inches—Won by William Burke (E-M-F), time 5:49½; second, John De Palma (Mercer), time 5:57 1-10; third, Plimpton (S. P. O.), time 6:16½.

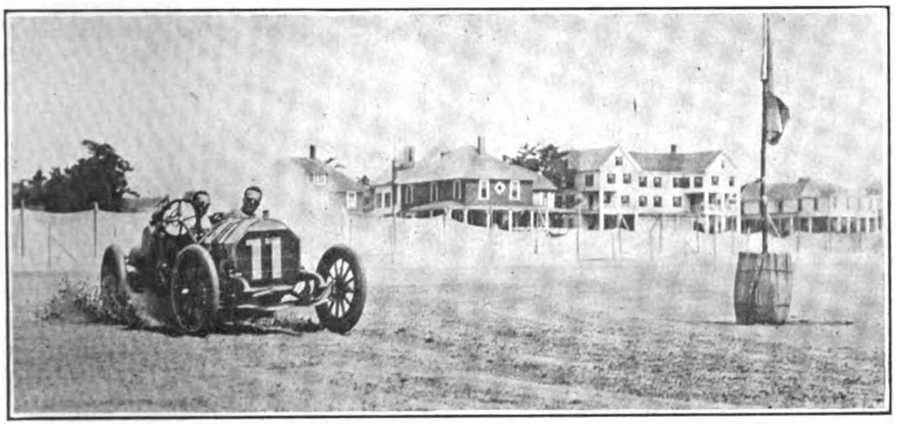
Five miles, for cars with displacements of 301-450 inches—Won by Jack Rutherford (National), time 4:32 3-10; second, Dave Lewis (Stutz), time 4:43 1-10; third, Neil Whalen (National), time 4:47 1-10; fourth, William Endicott (Schacht), time 5:02½.



100 miles, for cars with displacements of over 301 inches—Won by William Endicott (Schacht), time 1:36:41; second, Jack Rutherford (National), time 1:36:50 1-10; third, Neil Whalen (National), time 1:39:65 1-10.

Saturday, July 6th.

Ten miles, for cars with displacements of 231-300 inches—Won by Joe Nikrent (Case), time 9:54; second, John De Palma (Mercer), time, 9:59 3-10; third, Esleek (Lexington), time 12:13.



25 miles, Class E, run in two divisions, for cars of 161-230 and 231-300 inches. First division—Won by William Burke (E-M-F), time 27:10⅘. Second division—Won by Joe Nikrent (Case), time 25:29 1-10; second, Albert Hummel (Mercer), time 25:37 1-10.

Ten miles, free-for-all—Won by Louis Disbrow (Simplex), time 8:53; second,

LEWIS (STUTZ) WINNING THIRD DAY'S 100-MILE RACE

Digitized by Google

HUMMEL (MERCER) MAKING THE SAND FLY IN HIS 50-MILE RACE

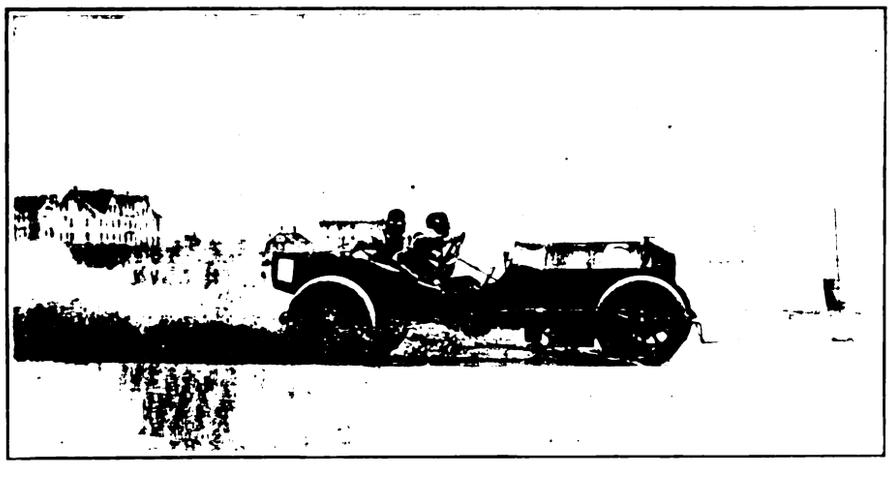
Basle (Bianchi), time 9:32 1-10; third, Neil Whalen (National), time 9:40 1-10; fourth, John De Palma (Mercer), time 10:22.

100 miles, for cars with displacements of under 600 inches—Won by Dave Lewis (Stutz), time 1:32:43⅗; second, William Endicott (Schacht), time 1:36:09; third, Harry Cobe (Jackson), time 1:50:11½.

Five miles, time trial—Louis Disbrow (Simplex). Time, 4:04½.

One mile, time trial—Louis Disbrow (Jay-Eye-See). Time, :30 1-10.

Four States Tour Leaves Hoosier City.



Laden, metaphorically speaking, to the brim with a live load of factory representatives, including both members of the advertising force and selling force, as well as mechanical experts, and each fortified with literature and otherwise prepared to exploit the combined advantages of motor cars built in the Hoosier State and the special advantages of the particular Indiana built car which he represents, 26 pleasure cars and two motor trucks left Indianapolis on Tuesday last, 9th inst., on the first leg of the Four States tour.

The tour, which is an annual event with the Indiana Automobile Manufacturers' Association, is a "boost Indiana" affair and is run with the avowed purpose of advertising Indiana in general and Indiana automobiles in particular. The contest side is eliminated altogether; the speed, which is determined by a pacemaker, who is chosen by drawing lots, will rarely, if ever, exceed the legal speed limit. Twenty days will be spent in traveling the 1,200-mile course blazed by the Great Western pathfinder car, which is doing duty as a confetti car, and which leads through Indiana, Ohio, West Virginia and Kentucky.

The automobiles which started in the tour are as follows: American (3), Pathfinder (2), Marion (2), Nyberg (4), Premier (2), McFarlan (2), Haynes (2), Maxwell (2), and 1 each Marmon, Cole, Great Western and De Tamble cars; also two trucks, a Whitesides and a Service.

Indianapolis Prize Money for "Also Rans."

What to do with the $2,100 which constituted the sum total which was to be awarded to the drivers who finished in eleventh and twelfth position in the 500-mile Sweepstakes run on the Indianapolis Speedway on Memorial Day, is a question over which the management of the speedway has been pondering ever since Ralph Mulford drove his Knox across the tape in tenth position at the close of the event. It was at first suggested that the sum be split and offered as a consolation prize to Ralph De Palma and Bob Burman, both of whom had contributed greatly to the interest which attached to the event, but on second consideration it was not deemed advisable to discriminate against the other twelve drivers who had dropped out through no wish of their own. It finally was decided to divide the prize money between the fourteen who did not finish, according to the number of laps he completed, and on this scale each man receives $1.9213 for each lap. De Palma and Burman, who completed 199 and 157 laps, respectively, will receive $382.54 and $301.54. The other drivers will receive sums in proportion. Knight and Ormsby, both of whom dropped out in the seventh lap, will receive the smallest amounts, $13.46 each.

ENDICOTT (SCHACHT) PLOWS DEEP AT TURNING POINT

Elgin Road Races Are Abandoned.

The life-line with which the Chicago Motor Club and the Elgin Road Race Association attempted to save the day by changing the annual Elgin road races from stock events, which they always have been, to non-stock events, has failed of its purpose, and the races, which were scheduled for August 23 and 24, have been definitely abandoned for this year, and in all probably for all time. Even under the new conditions, the entry blanks failed to "draw," and as only 10 drivers actually had "signed up," the Chicago Motor Club voted to divorce itself from the venture. Inasmuch as the Elgin Road Race Association, through Fred. Jencks, its representative, also has signified its intention of leaving the contests severely alone, the project is virtually dead. Though at one time it was rumored that an individual, whose name was not divulged, had purchased all the rights and privileges and would stage the contests without the aid of either of the organizations which in the past have managed them jointly, the story was promptly denied by Jencks, and there is scarcely even a remote possibility that anything of the kind will come to pass, though it is hoped to stage the events next year.

New York Enacts "Night Hawk" Law.

After it had lain on the shelf for several months, the New York Board of Aldermen, on Tuesday last, 9th inst., took up and passed the ordinance framed with a view of keeping closer "tabs" on "night-hawking" chauffeurs. The new ordinance will make the tracing of a delinquent chauffeur a simple matter for the police department, which has access to the books at all times. The ordinance in part provides:

"It shall be the duty of each and every keeper of a public garage to record in a book kept solely for such purposes, the time of departure from such garage of all motor vehicles kept for hire, giving the names and addresses of the owner and the driver thereof, the name and class of the vehicle, the license number of the driver and the vehicle, and the time of return to the garage of each such vehicle shall be entered in such book, and such reference book shall be open to inspection at all times to the representatives of the Public Departments and the Mayor's office."

FAST FLIGHTS ON WILDWOOD STREET

Freitag Does the Straightaway Mile in 43⅗ Seconds—Bauer Takes Two of Three Open Events.

Over a mile road, straight as an arrow, and innocent of both dust and bad spots, which leads through the very heart of North Wildwood, N. J., six speed events which comprised the Fourth of July program offered by the North Wildwood Automobile Club were contested on Thursday last. Fast flights naturally were to be expected under conditions which were nothing if not ideal, and the most pessimistic spectator was not greatly disappointed, for in at least two of the events the proverbial "mile a minute" mark was far surpassed, while "going some" was the rule of the day.

The honors of the day, although pretty well divided, went in greatest measure to Edward Bauer, who drove a Buick car and won both the free-for-all handicap, which was run in heats—Bauer's time for the first and final heats being 1:19 and 1:15, respectively—and a Class C event for cars with piston displacements of 160-230 cubic inches, in which he completed the mile in 1:19⅕. The best time of the day was made by Freitag, who drove the mile in a Fiat in 43⅗ seconds, or at the rate of 83.4 miles an hour. Freitag's time was made in the individual time trials and was a full three seconds better than the time of Streach, who drove his Chadwick down the straightaway in :46⅗. A match race between Harvey Ringler, in a Mercer, and C. C. Fairman, who piloted the Kline entry, resulted in a victory for the former, who covered the distance in 1:08 as against 1:29 by Fairman. A similar race between Irwin, who drove a Marion, and Earle, who drove an American, was won by Irwin, whose time, 1:08, was nine seconds better than that of the American pilot. John Menker finished first in the Class C event for cars with piston displacements between 301-450 cubic inches. Menker's time, :53, was the best time of the day made in competition. The summary:

One mile, for cars with displacement of 161-230 inches—Won by Edward Bauer (Buick), time 1:15⅗; second, M. Baker (Carter), time 1:16⅘; third, R. S. Smith, Jr. (Empire), time 1:19⅕.

One mile, match race—Won by Harvey Ringler (Mercer), time 1:08; second, C. C. Fairman (Kline), time 1:29.

One mile, for cars with displacements of 301-450 inches—Won by Menker (Kline); second, Knox (National); third, Thebaude (G. J. G.). Time, :53.

One mile, time trials—Freitag (Fiat), :43⅗; Menker (Kline), :46⅗; Streach (Chadwick), :50; Davis (Apperson), :53⅕; Knox (National), :56⅕; Woods (Benz), 1:00⅗; Irwin (Marion), 1.04⅗.

One mile, free-for-all handicap—Won by Bauer (Buick), 1:19; second, Baker (Carter), 1:19⅘; third, Smith (Empire), 1:21⅗. Second heat—Won by Ringler (Mercer), 1:06⅘; second, Irwin (Marion), 1:12⅕; third, Woods (Benz), 1:19⅕. Third heat—Won by Davis (Apperson), 1:06⅕; second, Freitag (Fiat), 1:06⅘; third, Thebaude (G. J. G.), 1:07. Final heat—Won by Bauer (Buick), 1:15; second, Davis (Apperson), 1:15⅗; third, Ringler (Mercer), 1:16⅗.

One mile, match race—Won by Irwin (Marion), 1:08; second, Earle (American), 1:17.

Effect of Garages on Adjacent Realty.

What effect, if any, the establishment of a garage has on adjacent realty is a problem which now is confronting the civic authorities in St. Louis, Mo., where the almost simultaneous application by seventeen individuals and concerns for permission to erect this type of structure has brought forth protests in certain parts of the city, and the question is one which gives promise of affording subject for considerable cogitation and discussion. Apart from the garages which wish to locate in the segregated sections, known as "automobile row," there are a number which wish to invade the residential and business parts of the city. The city fathers are unwilling to hamper business progress, and still do not care to make any unwise move. One clergyman opposes the placing of a garage opposite his church for obvious reasons, another citizen claims the establishments will reduce the value of near-by property and several complaining petitioners express great fear of the automobile shops, declaring that almost always they are fire traps and a menace to the neghborhood.

Automobile Horn as a Burglar Alarm.

Unusual and effective use for electric horns of the Klaxon type is suggested by a Chicago man who houses his car in a private garage not a great distance removed from his residence. The Chicagoan had been troubled by burglars, who, despite lock and bolt, had entered the garage and relieved the machine of such fixings as readily could be turned into money. After the third visit of the marauders, the sufferer had the garage wired and all the appurtenances of a closed-circuit burglar alarm system were installed save the gong, which was supplanted by the electric horn. When the thieves paid their fourth call such a volume of noise issued when the garage door was forced that the entire neighborhood was awakened, and the policeman on beat caught both intruders. The garage has not been entered since.

Hibner Heads Iowa Falls Club.

Charles G. Hibner has been elected president of the Iowa Falls (Ia.) Automobile Club. Other officers of the organization who were chosen at the annual election are: Vice-president, W. V. Shipley; secretary-treasurer, Dr. W. G. Morton.

BIG MONEY FOR MILWAUKEE EVENTS

Purse of $10,000 Offered in Grand Prize and $6,000 in Vanderbilt Cup Races—How It Is Distributed.

Perhaps the Grand Prize race will prove a mere "curtain raiser" for the Vanderbilt Cup race, as the promoters design shall be the case, but if it so proves it will not be that it lacks the glitter of gold; for from the dollars and cents standpoint the imitation of the French race is more attractive than the truly American classic.

The value of the money prizes which will go to the leaders in the Vanderbilt race, which will be run on September 21, amounts to $6,000, distributed as follows: $3,000, together with the possession of the Vanderbilt cup for one year and a donor's permanent trophy, to the winner; $2,000 to the second man, $1,000 to the third and $500 to the fourth. The race will go for 296.65 miles, which represents 34 circuits of the 8.725-mile course, and will be run as a Class E event, open to cars of Class C with piston displacements of 301-600 inches.

The money prizes which attach to the Grand Prize race amount to $10,000 in value, $5,000 of which goes to the winner, together with the trophy; $2,500 to the second man, $1,250 to third, $750 to fourth and $500 to fifth. The race will also be run over the Greenfield course at Milwaukee, the date being September 17. The rules simply require that the car carry two passengers; that a reverse gear be provided; the exhaust be not directed toward the ground; that the width of the car be not over 6 feet 2 inches.

For the newly inaugurated Pabst trophy, which will be open for Class C cars with piston displacements of 231-300 inches and which will go for 25 laps, or 218.12 miles, on Friday, September 20, and for the other, the Wisconsin trophy, which will be open for cars of Class C with piston displaceemnts of 161-231 inches and will cover 175.5 miles (20 laps) on the same day, the prizes naturally are not so large. The Pabst trophy is offered under a deed of gift similar to that under which the Vanderbilt is contested for, and carries with it a cash prize of $2,000 for the winner, $500 for second man, $250 for third and $125 for fourth. The Wisconsin trophy becomes the permanent property of the winner, who also receives $1,000, second $500, third $250, fourth, $125.

Milwaukee is preparing to accommodate a bumper crowd. Thirty-five thousand reserved seats are to be placed in the huge grand stand on the course, and there also will be staked off reserved parking spaces adjoining and in the vicinity of the grand stand, and 30,000 unreserved parking spaces. The sale of tickets for boxes, grand stand seats and reserved parking spaces will begin next Monday, July 15th. It is stated that already there are 1,000 reservations.

TETZLAFF WINS TWICE AT TACOMA

Evans, Poltun and Cooper Account for the Other Road Events—Flying Stones Cause Two Unusual Mishaps.

That well beaten trails across prairie sod can, when properly treated and thoroughly "manicured," supply a setting for a speed carnival which is surpassed by but few well paved road courses, amply was demonstrated during the two day speed carnival which was held on July 5 and 6 at Tacoma, Wash., in connection with the Montamaro Festo Carnival. The speed of the newly created course was proven when Ralph Mulford covered a single lap, which represents five miles, in 3:55, or at a rate of 84.5 miles an hour.

The events which were run on Friday and Saturday were the first of real importance the Great Northwest ever had witnessed, which, coupled with the fact that the races were but part of the program offered for the seven day "Feast of the Mountain" Carnival, made the attendance of a heart-cheering number of interested spectators a foregone conclusion. The course, which after many trials and tribulations was laid out within a stone's throw of the city, was just .033 of a mile short of being five miles in length. Although negotiations had been opened to secure the public roads some two months ago, complications arose which brought operations to a halt, and it was not until the last two weeks that the steam rollers could prepare the surface and the contractors' gangs ease off the corners to eliminate "hairpin" bends in the dirt highways.

If the contenders were not numerous, they did not lack class, and of the number Teddy Tetzlaff, the Fiat pilot, gave the best account of himself. He won both the 200-mile Class E event, which was run off Friday and in which his time was 2:54:31, and the 250-mile free-for-all, which was the only event staged on Saturday and in which his time of 3:47:00.45 was slightly better than 66.6 miles an hour. Tetzlaff's time in the shorter event, however, was better, and stands at 68.9 miles an hour.

The most interesting of the four events which were on the first day's program was the 200-mile event for cars with displacements under 600 inches, in which five entrants—Ralph Mulford (Knox), "Hughie" Hughes (Mercer), Teddy Tetzlaff (Fiat), Earl Devore (National) and Earle Cooper (Stutz)—all famous in varying degrees, started. Devore held the front until 18 of the 40 laps had been reeled off, when Mulford nosed his Knox into the premier position. It was on the seventh lap that Mulford had circled the course in 3:55, and it is not at all unlikely that he would have sooner gone to the fore had he not been delayed when his car skidded into a ditch on the 16th lap, and later he suffered a more unusual mishap. He held his position until a stone thrown up by Hughes's Mercer, which was about to pass, struck him on the head and temporarily blinded him. Tetzlaff, who had held his Fiat in second position, then assumed the lead and finished in 2:54:31. Mulford's mechanician, Chandler, had taken the wheel of the Knox when the stone struck the Knox pilot, and he drove it in good style into second place. Third place went to Earle Devore in the National. Hughes ran the Mercer into a fenee on the 39th round, but both he and his mechanician escaped injury.

The "baby" race, Class E, for cars with displacements under 231 inches, which went for 100 miles, proved "easy" for Evans, who drove one of the two "Flanders Special" cars which were entered, the same machines which participated in the Santa Monica road race last May and over which quite a rumpus was raised in A. A. A. circles. Evans's time for the 20 laps was 1:38:20. Towers, who also drove a Flanders Special, followed his team mate, leaving third position to Zoermann (Maxwell). Thus the order of things which was followed at Santa Monica was reversed in the Tacoma road race.

Poltun, who drove one of the three Mercer cars entered in the Class C event for cars with displacements of 231-300 inches, won a hollow victory when he brought his machine across the tape after having covered the 150 miles in 2:25:13. Both of his team mates, Bergdoll and Hughes, were eliminated by motor trouble, while Sebastian, who drove the Cole entry and was the only other contender, dropped out when the car caught fire, after having gone 12 of the 30 laps.

The medium car event, 150 miles for cars with displacements of 301-450 inches, went to Earle Cooper, who covered the distance in his Stutz in 2:15 flat. Second honors went to Devore in the National, while Rossi in the Pope-Hartford, who was the only other contender, finished last.

The single 250-mile free-for-all event which was run on the second day of the meet naturally proved the most interesting of the five which were offered by the Festo committee. It started with eight contenders, Tetzlaff and Verback driving Fiat cars, Hughes in a Mercer, Mulford in a Knox, Devore who piloted a National, Bergdoll, Cooper and Sebastian who respectively drove a Benz, Stutz and Cole. Verbeck finished in fourth position, while Earle Cooper drive his Stutz fifth over the tape.

Tetzlaff assumed first place as early as the 19th lap of the 50-lap affair and never was passed, although Bergdoll in a Benz, who took second place and finished in 3:50:49.85, over 13 minutes later than the winner, at times did look dangerous. Devore took third place, his time, which was made in the National, being 3:52:28.9. The other five contenders, including Mulford, who had sufficiently recovered from the injuries received the day previous, were strung out along the course.

The only accident of a really serious nature which occurred, and which in all probability will prove fatal to a spectator who had assumed a post of vantage in the limbs of a neighboring tree, was occasioned by a flying stone which struck the spectator and caused him to release his hold. He was seriously, if not fatally, injured by the drop which naturally followed. The summary:

Friday, July 5th.

100 miles, for cars with displacements under 231 inches—Won by Evans (Flanders Special), time 1:38:20; second, Tower (Flanders Special), time 1:39:04.35; third, Zoermann (Maxwell), time 1:42:19.5.

150 miles, for cars with displacements of 231-300 inches—Won by Poltun (Mercer). Time, 2:25:13.

200 miles, for cars with displacements of under 600 inches—Won by Tetzlaff (Fiat); second, Mulford (Knox); third, Devore (National). Time, 2:54:31.

150 miles, for cars with displacements of 301-450 inches—Won by Cooper (Stutz); second, Devore (National); third, Rossi (Pope-Hartford). Time, 2:15:00.

Saturday, July 6th.

250 miles, free-for-all—Won by Tetzlaff (Fiat), time 3:47:00.45; second, Bergdoll (Benz), time 3:50:49.85; third, Devore (National), time 3:52:28.9.

Oldfield Makes Records for Montana.

It was Barney Oldfield from A to Z at the four-event racemeet which was run at Butte, Mont., on Thursday, July 4th, in conjunction with a number of foot races, motorcycle races and an aviation meet. It marked his return to the track and to record making. Of the four races, Barney took the three in which he started, though in two of them he was only driving against time to establish new State records for both a single and for five miles, which for years was his "specialty." Oldfield drove a Christie car in his attempt to shatter the mile record, but the best he could do was 57 seconds flat, breaking the record by one-fifth of a second. He also drove a Cino five miles, his time being 5:07, which also is claimed to be a Montana record. Oldfield later steered the Cino in a ten mile match race with Lew Heineman, who piloted a Benz, and completed the distance in 10:44½, beating the Benz driver by half a second. The event in which Oldfield did not compete was a ten-mile owners' race, which was won by Arthur Hayes in a Pope-Hartford, who completed the distance in 11:11⅕. Second place went to Herbert Riley in a Ford, while J. Hayes took third position in a Chalmers.

At a meeting which resulted in the formation of the Flatonia (Tex.) Automobile Club, E. A. Ernin was elected president. The other officers are: Vice-president, F. W. Dusek; secretary, D. McKay; treasurer, F. F. Wotpkia.

"INDIGNATION" MARS MOROSS MEET

Peculiar Attitude of Iowa Boatmen Causes Crowd to Shrink Unprofitably—Burman, as Usual, Plays Star Part.

Indignation greeted the arrival in Davenport, Ia., of the troupe of professional racing drivers under the management of E. A. Moross on Thursday last, July 4th, where the racing men were scheduled to deliver themselves of a five-event race meet on the mile track. The indignation was the outcome of the belief on the part of the management of the annual power boat regatta, which also was billed to take place on the afternoon of the holiday, that Moross was an interloper and had come to Davenport to "cut in" on the crowd that might be attracted to the slower-going boat races. So high did the peculiar feeling run that the spectators at the track were few, most of them coming from outside of the city.

As is usual with Moross programs, the greater part of the interest attached to the three heats which were run for the Remy Brassard and trophy, two of which, the second and final, were won by Robert Burman in the Blitzen Benz, his time being 3:00⅗ and 3:05 for the respective heats. The first heat went to the Benz driver, E. A. McDonald, who completed the three miles in 3:07.9, after both Burman and Menenghetti, who piloted his Mercedes, had dropped out following a collision, which, however, was not of a serious nature.

Burman drove the Benz one mile in 52⅘ seconds, as against 59⅗ made in an Ohio by John Raimey. The other two events, for cars with displacements over 450 and under 600 inches, both of which went for five miles, proved easy for Raimey, who respectively defeated Bishop (White) and Burman (Cutting), finishing in 5:10⅘. The summary:

Five miles, for cars with displacements of under 450 inches—Won by John Raimey (Ohio); second, Burman (American). Time, 5:44⅕.

Three miles, for Remy Brassard and trophy. First heat—Won by E. A. McDonald (Benz). Time, 3:07.9. Second heat—Won by Robert Burman (Benz); second, Louis Menenghetti (Mercedes); third, E. A. McDonald (Benz). Time, 3:00⅗. Final heat—Won by Robert Burman (Benz); second, Louis Menenghetti (Mercedes); third, E. A. McDonald (Benz). Time, 3:05.

One mile, time trials—Robert Burman (Benz), time :52⅘; John Raimey (Ohio), time :59⅖.

Five miles, for cars with displacements of under 600 inches—Won by John Raimey (Ohio); second, Robert Burman (Cutting). Time, 5:10⅘.

Special Speed for State Fair Week.

While the volume of traffic in various thoroughfares is oftentimes the basis of fixing a speed limit for vehicles, Hutchinson, Kan., has gone the custom one better and, having passed a speed ordinance covering other local conditions, has declared that while the Kansas State Fair is on in that town the motorists will be governed by a special speed limit which, for Main street, is eight miles an hour. The new ordinance clips five miles an hour off the former limitation and places the figure at ten miles an hour on all streets, in contrast to the former rule of ten miles on Main street and fifteen on side streets.

Plaint of the Fire Engine Driver.

"Things ain't what they used to be," remarked the driver of one of the big horse-drawn steam fire engines of the New York Fire Department, apropos of fire-fighting apparatus and automobiles generally. "It used to be that when we went along a street, hittin' it up to beat the band, pretty near everything in front of us would make for the side streets or squeeze up agin' the curbs to let us go by, an' pretty near everything behind us would be left almost out o' sight. Nowadays when we get behind a bunch of automobiles they just open up a little an' leave us behind, feelin' like we was anchored, an' many a time I've seen a loaded motor truck come up on us from behind an' slow down to keep from buttin' into the back end of the ingine. This automobile business sure has changed things a lot, an 'it's just about time for the fire department to do some changin', too. Horses used to be all right, but now—well, the sooner they go the better."

Dawson to Become Vaudeville Star.

Having obtained fame sufficient to make his name well known throughout the United States, Joe Dawson, winner of the Indianapolis Speedway Sweepstakes, May 30, has followed in the lead of numerous other celebrities and is going on the stage—at least, according to an announcement sent out. E. C. Shuart, who managed the Speedway events, will be manager of the venture. Dawson's, or rather Shuart's, scheme is to appear at various fairs in exhibition drives and in theaters, where he will appear at the wheel of the winning National car, while another part of the exhibit will be a lecture and a half-mile of moving picture film.

Can a Car be Exempt in Bankruptcy?

Whether an automobile may be a tool or an instrument of trade and thus come within the exempt property class in a bankruptcy proceeding is a point which now is puzzling Judge Munger in Lincoln, Neb., and which also is causing some worry for Arthur W. Dorland of Bennett, Neb., because the latter is making a strenuous fight to keep his car, while his creditors are equally determined that it is not a tool and therefore should be used to swell the creditors' fund. Dorland is an implement dealer, and in traveling about the country repairing machinery used his car.

BURMAN AND RAIMEY PLAY SEESAW

Take Turns in Cleaning Up at Fort Wayne's Meet Promoted by Moross—Burman Retains Remy Brassard.

Although the scent of victory was strong in the nostrils of Louis Menenghetti throughout the better part of the three miles over which he drove his Mercedes in the first heat for the Remy Brassard and trophy on Sunday last, July 7th, at Fort Wayne, Ind., it was but the sense and not the substance which the West Indian partook of, for his sole competitor, Robert Burman, nosed him out on the home stretch and poked his Benz over the tape just five feet ahead of Menenghetti. Burman's time for the three miles was 2:52½. The Cuban did not have a chance in the second heat, for motor trouble easily put him out of the running. Burman, however, finished in 2:54½. Since by taking the first two heats, Burman clinched his hold on the "meal ticket," the third heat was eliminated.

Of the other five events which were incorporated in the program offered by E. A. Moross all save one—three miles, for cars with displacements under 450 inches, which was won by John Raimey (Ohio) in 3:20—went the way of the Remy Brassard heats. Burman not only established a new track record for a mile, which he drove in 53¼ seconds (old record 53½, held by Oldfield), but he also "cleaned up" a Class E event which went for five miles and which he completed in 5:12, and a three mile event, for cars with displacements of under 600 inches, which he won in 3:21, driving against Raimey in an Ohio and a local man, Kyle, who piloted a White. Burman used the Cutting in both of these events. In the time trials for a single mile, which completed the program, Burman, driving the Benz, covered the distance in 54½ seconds as against 57 made by Menenghetti. The summary:

Three miles, for cars with displacements of under 450 inches—Won by John Raimey (Ohio); second, Kyle (White). Time, 3:20.

Five miles, for cars with displacements of under 600 inches—Won by Robert Burman (Cuttng); second, John Raimey (Ohio); third, Kyle (White). Time, 5:12.

One mile, time trial—Robert Burdan (Benz). Time, :53¼.

Three miles, for Remy Brassard and trophy. First heat—Won by Robert Burman (Benz); second, Louis Menenghetti (Mercedes). Time, 2:52½. Second heat—Won by Robert Burman (Benz); second, Louis Menenghetti (Mercedes). Time, 2:54½.

Three miles, for cars with displalements under 600 indhes—Won by Robert Burman (Cutting); second, John Raimey (Ohio); third, Kyle (White). Time, 3:21.

One mile, time trials—Won by Robert Burman (Benz), time :54½; second, Louis Menenghetti (Mercedes, time :57.

ECONOMICAL OPERATION VS. EXCESSIVE POWER

Engineer Cameron Takes Up Cudgels in Favor of Small Motors Running at Economical Speeds and Transmitting Power Through Four-Speed Gearsets—Argues That Big Motors Waste Fuel Most of the Time, and Explains Why—Points to Four-Speed Gear as Next Popular Improvement.

That, as has more than once been pointed out by engineers both in America and abroad, there is logic in increasing slightly the final gear ratio between the engine and the road wheels, particularly in the lighter-powered pleasure vehicles which steadily are increasing in numbers, has again been advocated, though not all of such advocates are as unqualified in their opinions as is W. H. Cameron, who for a number of years has been chief engineer to the Willys-Overland Co. and who at present occupies a similar position with the Michigan Buggy Co. Cameron favors particularly the adoption of the four forward speed change gear mechanism—or transmission, as that portion of a car somewhat erroneously has come to be styled—for motor cars in general, and specifically for the small-powered car, which at present, he says, cannot operate efficiently with less than four forward speeds.

The analogy between the four-speed change gear mechanism and slightly increased final gear ratios between the engine and the road wheels should be perfectly apparent without the necessity for lengthy explanations, though in view of the importance of the subject it is not irrelevant briefly to summarize the connection between the two. With the present style of three-speed change gear mechanism, it is absolutely essential that the final gear be such—3½ to 1 is general, though even 4 to 1 is fairly common—that it may be used almost constantly, up hill and down dale. That is to say, the operator must be able to negotiate every hill except the steepest without recourse to second speed, inasmuch as second speed is so low as to cause an excessive strain on engine parts, due to high engine speed, and an excessively high fuel and oil bill for the same reason.

Therefore, it follows that if the final gear is low enough to permit its being used practically constantly, without change for ordinary hills, there must be a great amount of distance covered when the gear is too low for either engine efficiency or economy of fuel. Under such conditions for a car speed of, say, 30 miles an hour, the engine really is running at a greater speed than is good for it as a steady diet. Short periods of high engine speed are not detrimental, of course, for nearly every engine is designed for just such contingencies. But no ordinary touring car engine is designed for continual use at very high speed. Moderate engine speed is conducive to longevity and, all things considered, it is the change gear mechanism that controls, directly, the speed of the engine.

With the four-speed change gear mechanism, on the other hand, it is possible slightly to increase the final gear ratio between the engine and the road wheels, for the reason that the third speed—which is higher than the second, though not quite as high as the third speed in a three-speed gearset—then may be used for ordinary, and in many cases for extraordinary, hills, while the direct drive is used for slight inclines and for level running. The combined effect, of course, is apparent: The engine operates at slower speed on level roads or slight inclines when high gear is used, and it also operates at slower speed on steeper hills when third speed must be used; and the car speed in any case may be a little greater (if necessary) without the necessity for racing the engine at excessive speeds. Despite the advantages of slightly increased final gear ratios, however, it is not possible to obtain them unless a four-speed change gear mechanism is used, and it is not unlikely, therefore, that Cameron's prognostication to the effect that before long all good cars will be so equipped will be realized.

"It may sound strange," he says, "when I make the prediction that the next radical change in automobile engineering will be the general adoption of the four forward speed transmission. By that I mean that in my opinion the four-speed transmission is bound to become generally used in all good American cars. To-day it is found in this country only in the highest priced cars. You can count on the fingers of one hand the cars selling under $3,000 that now have four speeds forward. Abroad, where special reasons have forced the use of the four-speed transmission in the large majority of cars, its advantages are better understood.

"One reason for its use on foreign cars is the extremely small bore of cylinders, due to the fact that the tax is graded by the size of the bore. An American car of more than 4-inch bore has little demand in England, where a bore of 3 inches and a fraction is generally used with an extremely long stroke, to give the maximum horsepower. Under such conditions the four-speed transmission is positively essential, both to economize the power and to gain the required flexibility of control. Its use under these conditions, however, only serves to illustrate the actual money saving in fuel and the lessened strain upon the machine, as well as the advantages in driving which will come with the widespread adoption of the four-speed gear box in America. For the same engineering principles apply in our case as in theirs.

"Before passing the point of economy, let me say I believe that the tendency in America will be decidedly toward smaller bores. This is due to the fact that everybody knows gasolene is becoming scarcer, and is sure to mount in price. I think the small bore is coming, even with the effort to popularize the six-cylinder car. The popular six-cylinder car of the future will be one with about the same piston displacement as the standard fours of the present.

"The four-speed gear box has been confined to high priced cars in America, primarily because of its prohibitive cost. Engineers, and I may say manufacturers, almost unanimously admit the great advantage of four speeds over three, but the cost question has caused the delay, until the demand of car buyers has become imperative. It means a complete change of design—more gears, wider gear centers—a big expense for the improvement, when all are totaled. But the advantages to be gained from it are certainly so manifest, so great, that it is a question of months only when it will be generally accepted. And with our roads, the four-speed transmission comes to general practice none too soon.

"Motorists now generally realize that the life of a car depends upon its use and abuse. It does not take a car owner long to reason to the fact that making a car put forth every ounce of power on frequent grades is highly detrimental. 'Learn to control your car exclusively by the gas, as far as possible,' says the instructor in motoring to the student. The salesman in ninety-nine cases out of a hundred says the same thing to the beginner who has purchased his car. Everybody who gives advice on running a car says it, thereby admitting that something is wrong or is lacking in the transmission. Yet everybody realizes on a moment's reflection that the transmission is the logical first means for the control of the speed. It takes long experience and special aptitude—I may say genius—for driving to know just how far to throttle in regulating a car by gas. Few ever learn it perfectly. The driver who does it with any degree of skill knows his car like a human friend and brother, and is also guided by some sixth sense of intuition.

"With the great majority this dependence almost entirely on the gas for regulating

Digitized by Google

the car is a matter of guesswork. It is disastrous not only to the pocketbook but, in not a few cases, to human life. It costs money to pull the engine speed down until the car almost quits on high, and then race the engine to pick up on second, as is so commonly practiced. We have grown used to the sight of the driver on high gear killing his motor at street crossings, street car tracks and railroad tracks by throttling down before he is successful in getting his clutch out.

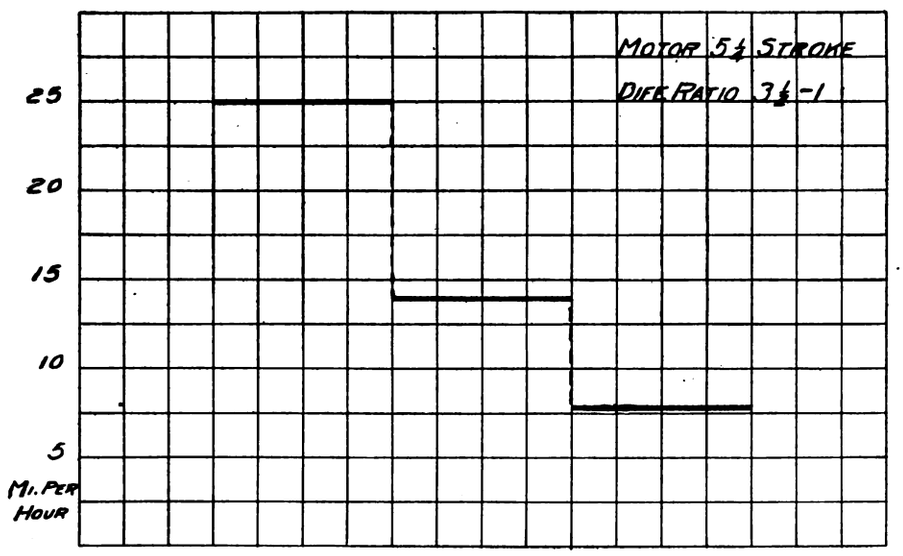

FIG. 1—SHOWING "GAP" IN ORDINARY THREE-SPEED TRANSMISSION

"If instead he slips into third speed on a proper four-speed transmission, he has a gear ratio which is practically the same as a 4½ to 1 rear axle, having which, as one knows, permits the car easily to be throttled down to two or three miles an hour, and still pick up quickly. By this time it should not be necessary to explain that the basic purpose of four-speed transmission is not to satisfy a mania for more speed. This was a common error when the four-speed transmission was rare practice.

"The four-speed transmission provides an efficient, feasible and logical control of the car—a control not based on guesswork, but upon an accurate, proved and dependable gear box, built in accordance with universally acknowledged mechanical principles, and in accordance with the best engineering practice the world over. It provides this control without wasting the fuel—without racing the motor, and consequently with far less vibration. It relieves the motor of undue strain, especially in taking heavy grades. With four speeds (the direct drive being on the fourth) the long sand stretches, the heavy roads, the miles of axle-deep slush, the hills and mountains may be negotiated without fear of punishing the motor, in the way that now works havoc, and shortens by years the life of the best car built.

"Grade climbing is one of the problems most satisfactorily solved by the four-speed gear box. Every motorist knows that unless he has an engine on which he can depend for a practically unlimited pull, he will find the inclination of many grades just a trifle too much for his top-speed. On such a grade with a four-speed gear box he can drop to third speed and it takes his car up like a bird. With a three-speed gear, he has to drop from top speed to second—and he makes an awful drop—in fact, second speed is almost 50 per cent. lower than high.

"The same condition is encountered in many roads which are just a little too heavy for top speed, although the car is actually capable of much better speed on these roads. We shall understand the necessity of the four-speed transmission more perfectly if we say that, while the speed ratios of a proper four-speed car are 1, 2, 3, 4 (the fourth being the top speed), the speed ratios of a three-speed car are really 1, 2, 4—the gap between second and high speed being so great that there is really no third speed. So when we put in a four-speed gear box we actually are adding a third speed to the car.

"The greatest question in four-speed transmission is the ratios of the gearing, or the number of times the motor must turn over to the number of revolutions of the rear wheels. The subject has engaged the attention of the leading engineers in Europe and America for several years; but it is only lately that they have practically agreed as to the direct drive.

"There are two types of four-speed transmissions: One direct on third speed, the other direct on fourth. The latter is generally conceded to be greatly in advance of the former. This is overwhelmingly proved by the practice on the great majority of cars now using the fourspeed gear box. Of 157 four-speed foreign cars, 132 have the direct drive on fourth. Of the American cars now using four speeds, 75 per cent. have the direct drive on the fourth. In fact, as the four-speed gear box gains in favor the indirect fourth will drop out overnight.

Table No. 1.

Speed.	Ratios Transmission.	Ratios Engine to wheels.
3	1.00–1	3.50
2	1.80–1	6.30
1	3.20–1	11.20
R	3.88–1	13.58

Table No. 2.

Speed.	Ratios Transmission.	Ratios Engine to wheels.
4	0.86–1	3.01
3	1.00–1	3.50
2	1.76–1	6.16
1	3.40–1	11.90
R	4.60–1	16.10

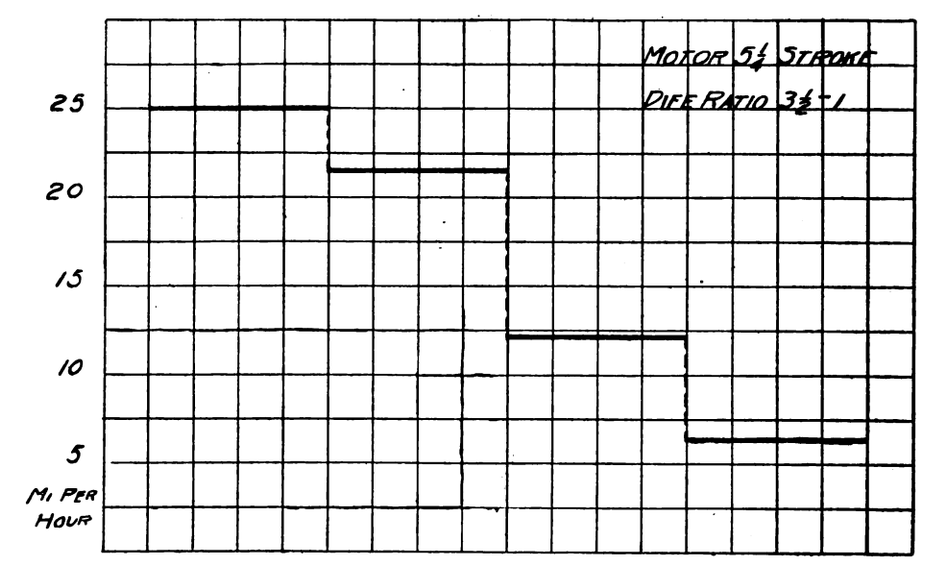

FIG. 2—FOUR-SPEED TRANSMISSION WITH INDIRECT FOURTH

Table No. 3.

Speed.	Ratios Transmission.	Ratios Engine to wheels.
4	1.00–1	3.50
3	1.29–1	4.51
2	2.10–1	7.35
1	3.76–1	13.16
R	4.57–1	15.99

"A study of the accompanying tables and diagrams will show the difference at a glance. Table No. 1 shows a common three-

Digitized by Google

speed transmission which is about what is fitted to 85 per cent. of the threespeed cars. It will be noted that 3½ rear axle gear ratio is used in all three tables. It will be noted also that in this transmission the first or low speed is only 11.20 to 1. This is the reason that so many cars are forced to back over the stiffer grades if there is no other way round. The reverse, of course, is lower. This is the result of transmission design.

"Take the next table now, which is No. 2. It shows a transmission of a well known and popular car. This is for the motorist who thinks he wants to burn up the roads, and who buys a car with an indirect fourth. He overlooks the fact that he loses almost all that he thinks he gains, through the inefficiency of the gears, and has two speeds which are almost alike. He has not much better second and low than his friend with the three-speed.

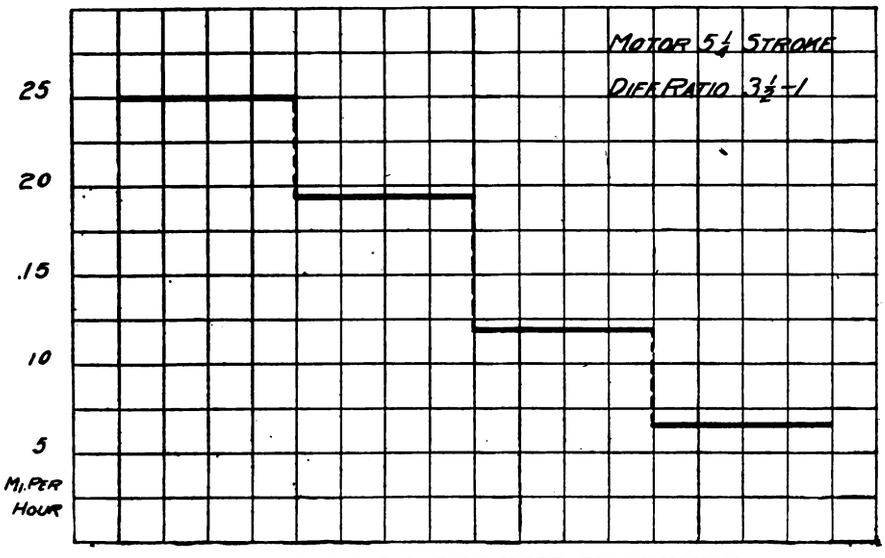

FIG. 3—CAMERON'S IDEAL FOUR-SPEED TRANSMISSION

"The ideal transmission, in my opinion, is shown in table No. 3. It will be seen than, when it is necessary to change from fourth to third, a speed is obtained which enables the car to go over the hill at a fairly good rate. Also note that the second in this is almost between the first and second of the others, consequently if the car is fitted with a good clutch, the operation for all ordinary driving resolves itself down to a three-speed job (as the second can be used for starting on the level), leaving the extremely low first and reverse for emergency.

"Taking all these facts (and the showing of the tables and diagrams herewith) into intelligent consideration, everyone must realize that four speeds, with the direct drive on the fourth, is the immediate step in the evolution of the leading cars.

Mysterious leaks in the high-tension part of an ignition system often can be detected by running the motor in the dark, when the escaping current will illuminate its own pathway.

DAIMLER ADDS THREE-TON TRUCK

Newest Product of Noted British Manufacturer Has Silent Chain Transmission and Worm Drive—Other Features.

Having obtained an enviable reputation and the King's patronage for its poppet valve engine pleasure cars, both of which have continued since the adoption of the Knight sleeve valve engine for all its products, the Daimler Motor Co. of Coventry, England, which was the first company to exploit the Knight engine, has, within the past few months, formally entered upon the production of commercial vehicles for road work and also for agricultural purposes.

At present the complete line of commercial vehicles includes five chassis varying in capacity from one to five tons and two agricultural tractors of 36 and 100 horsepower, respectively, the latest addition to the line being a three-ton capacity Knight engine chassis which is suitable for either omnibus work or inanimate freight transportation, and which numbers among its unusual features a chain change speed mechanism, worm drive and leather universal joints. Another of the unusual features of the chassis is that it is equipped with semi-elliptic springs in the rear and three-quarter elliptic springs in front. The upper quarter member of the front springs, however, is at the rear end of the springs. In general, the engine differs but little from the other Knight engines which are manufactured by the Daimler company, the cylinders being cast separately and having a bore and stroke of 110 m.m. and 150 m.m., respectively. The whole construction, however, is rugged, as becomes a product which is expected to withstand severe strains.

As an indication of the thoughtfulness of the designing engineers in providing against contingencies over which they have no control, the magneto is completely enclosed in a water and dust tight aluminum casing. The drive from the engine is transmitted to the propeller shaft through the intermediary of a "silent" chain change speed mechanism similar to that which is used in the fleet of 'buses operated by the London General Omnibus Co. Three speeds forward are provided, with direct drive on high, and the reverse motion is obtained by means of orthodox pattern spur gears. The clutch is of the leather-faced cone variety, and is no less than 21½ inches in diameter. The final drive is by overhead worm to live axles, nothing of a startling nature being included in this portion of the car, with the exception that beneath the axle housing, with which they are formed integral, there are conveniently located "feet" or jack rests, their purpose being to eliminate the chance of injury to the axle casing by an ill placed jack.

Making Old Piston Rings Serviceable.

In case piston rings show very poor bearing surfaces and it is not possible to obtain new rings, an improvement often can be made by easing the high spots of the rings with a very fine file, which must be new and sharp in order to get through the almost glassy "skin" formed by friction with the cylinder walls. The rings can be tried in the cylinder by slipping them into the bore while they are removed from the piston. It is rather a difficult job to do, and no very fine results can be expected; but by careful work it is possible to very considerably reduce compression losses, avoid unequal cylinder wall wear and increase the available power of the motor. The finishing touches should be put on with a piece of very fine emery or crocus cloth on a flat piece of wood, and the greatest care should be taken to clean off every trace of the abrasive powder from the rings before allowing them to touch the cylinder walls. Incidentally, if the rings are in such condition that they have not the springiness necessary to press them against the cylinder walls, no amount of surfacing will do them any good, and while peining the inner circumferences would perhaps help some, the operation is almost certain to result in the breaking of the brittle cast iron.

Driving Acid Out of Storage Batteries.

In equalizing the electrolyte in the different cells of a storage battery, it should be borne in mind that the acid must be in the cells somewhere, even though the hydrometer reading does not show it, unless some of the liquid has been spilled and the cells filled up with water. As the acid is not in the electrolyte, it must be in the plates, and this being the case, it remains to drive it out of the plates by long, slow overcharging, which will gradually bring up the readings of the "low" cells. The fact that the liquid has evaporated, necessitating the filling of the cells with water, means nothing, for the water evaporates, leaving the acid behind.

SPEAKS UP FOR THREE-CYLINDER

Foreign Advocate Thinks it was Abandoned too Soon—Its Several Advantages as he Sees Them.

"Should the three-cylinder engine be revived?" asks a writer in a foreign periodical. Logically, there seems no real reason why it should be revived, particularly in view of the notable advance in the number of six-cylinder engines that has been made and is being made every day, though, if the question is examined from every point of view, it appears, parodoxically enough, that it might be revived to some purpose, after all. Of course, there is quite a number of three-cylinder two-cycle motors on the market that are giving excellent service, but there are no four-cycle three-cylinder motors regularly used in cars to-day and it is many a long year since the last of them chugged over the roads.

It is difficult to ascribe to any one cause the complete disappearance of the three-cylinder four-cycle engine, which only a few years ago made a bold bid for popularity. Probably the chief, if not the only, reason for its quick demise can be attributed to the rapid rise of the four and six-cylinder motors. However, despite the perfection of these two types of motor and their universal adoption for even the smallest powers, it would seem that there may have been some slight oversight of the advantages of the three-cylinder engine in the possibility of its adoption for light commercial vehicles, for instance, where the uneven torque and vibration of the one- or two-cylinder engine constitute its principal drawback to more general employment.

Within the past year or so both of these types of engines have been brought to a higher state of perfection than ever before and their objectionable features have been rendered less objectionable by several hundred degrees. Development has been particularly noticeable in the case of the two-cylinder engine which has been adopted by a large number of light commercial vehicles. Here, though vibration has been reduced to the minimum possible, in view of the constructional difficulties imposed by the type, irregularity of torque still remains and is one of the things which cannot be overcome, except by the addition of at least one more cylinder.

"Those who understand the principle of the two possible arrangements of the two-cylinder engine (excluding the V type)," says the foreign writer who asked the question, "will grant that if comparatively steady torque is obtained by having the explosions occur at equal intervals, a bad mechanical balance results as the two pistons move up and down simultaneously. If, on the other hand, the even torque is sacrificed to obtain a better mechanical balance by having one piston moving up while the other is moving down, it is nevertheless questionable whether there is any actual gain. Consequently it is to many persons a case of four cylinders or none."

"Yet," he continues, "if any one seriously asks why the three-cylinder engine disappeared, it is extremely difficult to get a reasonably satisfactory answer. It is important to remember that the three-cylinder engine has a power stroke for every two-thirds of a revolution of the crank shaft, and from the point of view of mechanical balance the three-cylinder crank arrangement would seem to be ideal, because instead of the crank throws being in the same plane, as in the four-cylinder, we have the throws arranged at 120 degrees apart, which constitutes practically a no dead-center system. True, there is a slight overlapping of the stroke of one cylinder into the stroke of another, which must mean a small sacrifice of efficiency, but surely the excellent mechanical rotary balance of the three cranks must amply compensate for this.

"There is no apparent difficulty with the ignition or carburation for the three cylinders. Certainly, with regard to the latter, the general arrangement of two-cylinder engines offers serious difficulties, mainly because of the unequal suction effect on the carburetter. If I were asked what my point of view is as to the ignoring of the three-cylinder engine I would suggest that it is the extra work involved in making the three-throw crank as compared with the four-throw. This latter, as anyone can see for themselves, is a comparatively simple piece of work.

"The three-throw crank, however, is a very different problem. Furthermore, there is the question of arranging for intermediate bearings; this is relatively a difficult matter compared with the four-cylinder crank. The three-cylinder engine, in the view of many of those who used it in the old days, ran even superior to the four-cylinder, and in the matter of climbing hills, there are those who say that no four-cylinder they have used comes up to the old three-cylinder in the point of uniformity of torque, and that the three-cylinder was the next best to the six-cylinder. Therefore I submit that the three-cylinder engine is a type which might with the greatest advantage be revived. It must be remembered that the machine tools available for the making of crankshafts are far ahead of any used, say, five years ago, and I venture to think that if it be the fact that the crankshaft problem is the real one, it should not be in these days of advanced types of machine tools a difficult one to overcome.

"The three cylinders, 'en bloc,' would occupy little more room than the present two cylinders, so that from the point of view of compactness no fault can be brought against it. It ought also to make a lighter engine than the four-cylinder of equal power. Whether it would be as cheap or cheaper to make than a four-cylinder is a question which is open to discussion, because presumably more time and money would have to be put into the making of the three-throw crankshaft. Whatever difficulties may appear in the way of its revival, the need for an alternative to the four-cylinder will unquestionably be felt, and the three-cylinder is well worth consideration."

"Little Six" Added to Knox Line.

By way of supplying the demand for a lighter six-cylinder model built along substantially the same lines as its older and heavier six-cylinder model, the Knox Automobile Co., Springfield, Mass., whose reputation has been spread no less by the excellence of its pleasure cars than by the dependability and durability of its commercial vehicles and fire apparatus, has added to its line a new model which is to be known as the Knox "little six." Though the new car bears all the Knox earmarks that have become familiar, it differs in several ways from its prototypes. Perhaps the most noticeable difference is in the radiator, which is of the pointed V-type, which gives promise of attaining popularity. The motor is rated at 46 horsepower, the cylinders measuring 4⅜ x 5½, and among other noteworthy features reflecting the latest ideas in up-to-date design, is equipped with "silent" chain driven cam and magneto shafts. Bodies are the usual roomy, easy riding creations and are mounted on a chassis of 130 inches wheelbase. The price of the new car in any of several open type bodies and including complete equipment is $4,350; with limousine or landaulet bodies the prices are $5,350 and $5,400, respectively.

Chalmers Begins Factory Enlargement.

Supplementing the addition of a two-story shipping building and several new test sheds, the Chalmers Motor Co., Detroit, Mich., has found it necessary still further to increase its manufacturing facilities, and operations immediately will be commenced on a four-story wing which will serve as a connecting link between the assembling and machinery buildings. The new structure, which is to be of reinforced concrete and steel, 191 x 71 feet, with 55,000 square feet of floor space, is but the beginning of extensive expansion which shortly will be undertaken. Arrangements also will be made for the erection of an additional building of the same size and shape as the three already in use, which are 60 x 400 feet and four stories in height. It is estimated that the new building will cost in the neighborhood of $75,000 and that its equipment as planned at present will bring the total valuation up to between $150,000 and $200,000.

Venezuela Adopts the Metric System.

Venezuela has adopted the metric as the official system of weights and measures, and has made its use obligatory in the courts and other public offices. An exception is made in the case of documents originating in a foreign country.

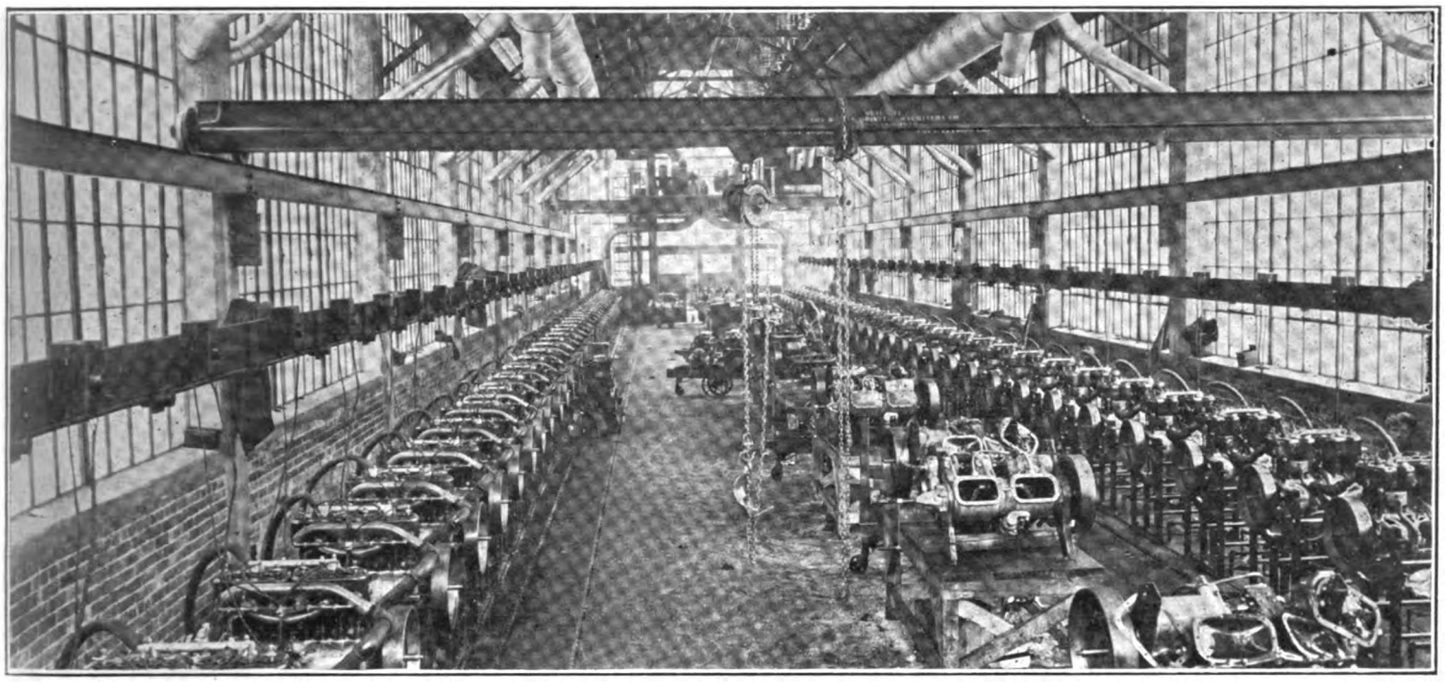
INCREASING FACTORY EFFICIENCY

How Manufacturers Raise Standard of Workmanship and Output Simultaneously—Diverse Factory Processes.



To those who never have had the opportunity to view an automobile factory going "full blast," so to speak, the sight never fails to prove an impressive, if not an awe-inspiring, one. The same statement applies in the case of those who perchance may have seen one factory and only one. For the variety in methods of increasing efficiency and output and raising the standard of workmanship simultaneously almost is legion. Each factory production manager or efficiency engineer has his own particular ideas regarding the best way of accomplishing results.

It is likely that nearly every one who drives a car realizes in a vague sort of way that certain parts can be made and finished, and are made and finished, a great deal better by machinery than by what has come to be styled "old-fashioned" hand methods. For instance, there are few who do not know of full automatic screw and bolt machinery—machines that turn out perfectly finished screws and bolts and nuts literally by the thousand without the necessity for human help other than that which is required to set and start the machinery. All these machines are absolutely automatic in operation. One man runs three of them, as a rule. Or, rather, the three machines keep the one man running to carry away the finished products. Some of them complete one operation before commencing the next, and others complete three or four operations all at the same time. Still others turn out completely finished parts on which nine operations are completed at the same time. Needless to say, under the old regime the time required for one man to complete the nine operations, requiring nine alterations of tool and machine setting, would have been far more than nine times as long as the machine requires. This is merely one little instance of the manner in which efficiency has been increased—the cost of producing the parts is approximately one-ninth the cost of machining them by hand.

And where automatic machinery is not used or cannot be used by reason of the work in hand, the ultimate result is much the same, for practically everything is machined in jigs. For instance, some small part, such as a bell crank, requires to have three holes drilled in it. It is fastened in a jig by means of only one screw and a wing nut, and the operator places it alternately under the three spindles in a gang drill. Thus the work is done in but a fraction of the time that ordinarily would be required if each hole had to be "spotted" first and drilled afterward. Often a great many holes of different sizes are drilled at once. The gear case forms an excellent example of this kind of work. The finished aluminum casting is clamped in a jig, a templet is placed over the surface to be drilled, and all the operator has to do is to set the drill to work. Trained mechanics scarcely are necessary, for practically nothing is left to the judgment of the operator, who has only to set his templets and start the machinery.

That there are practically no planing or shaping machines in use in any of the factories to-day scarcely need cause surprise, for such machines are inefficient in that no work is done on the "return" stroke. Their place has been taken by milling machines which work steadily and without loss of time or motion. And some of the work that is done in these machines is nothing short of remarkable. As an example of what may be accomplished by constantly seeking to establish better methods, the manner in which cylinder castings are machined in the Ford plant is illuminating. The machine that does the work is not inordinately complicated—as is some of the other automatic machinery—but its capacity for work and its accuracy caused more than one of the engineers who attended the recent S. A. E. convention in Detroit to pause and wonder. The machine mills three surfaces on no less than 12 cylinder castings at one mouthful, so to speak. The four Ford cylinders, be it remembered, are cast in a single block. At other plants, cylinder castings are machined in much the same way, as are crankcases, gear boxes and other bulky castings which require to be surfaced on three or more sides. Needless to add, no matter what may be the part undergoing treatment, it first is clamped securely in a jig, and not the least interesting part of the jigs themselves is that seldom are more than two screws required to hold the work. In most cases a single screw, usually provided with a wing nut, suffices. Thus it requires the minimum of time to make a part ready for machining.

To the layman who may have looked at his lubricating oil bill askance, the first impression of almost any of the factories is that a really tremendous amount of oil is wasted. On nearly every cutting tool a stream of oil as thick around as a man's finger impinges. Where oil is not used soda water takes its place. Contrary to the

MOTOR TESTING HOUSE IN THE STUDEBAKER FACTORY SHOWING THE TRAVELING ELECTRIC ENGINE STARTER

Digitized by Google

thoughts of the visiting motorist, however, the oil is not "used up" in the sense that it is lost after having slopped all over the work. Instead it drains downward through a series of screens into a sump in the bottom of the machine and is pumped up and over the work again. Each machine carries its own oil pump and the oil is maintained in circulation constantly and thereby cooled. As a matter of fact, there is remarkably little waste, all things considered. Incidentally, to the man who has had occasion to do odd jobs on a small lathe, the cutting speeds and the depth of cut taken off prove a revelation. High speed tool steel is used, as a matter of course; that is to say, the tools hold their edge and temper even if run so hot as to be dull red. In turning down gear blanks, for instance, a cut almost a quarter of an inch in section is taken off and the lathe tool soon becomes so hot that the black cloud of oil smoke that overhangs the machine all but obscures the work. Though it may startle the uninitiated to see the smoke, and the rate at which the machines are forced, nothing feazes the operator, for the table of cutting speeds is laid down by the factory engineer, who knows the exact limit to which the different machines must be worked in order to obtain the greatest efficiency. The steel is cut off just as easily and with just as little fuss as so much cheese is cut. It is true that there is a really terriffic strain on the machinery, but the machinery is heavy and is designed to withstand the strains; it operates day in and day out without falter.

Methods of testing and "running in" engines scarcely are less interesting than production methods, particularly, as is the case in the Ford plant, when the number of finished and tested engines turned out each day runs into the hundreds; on the day the S. A. E. delegation visited the plant it was announced that just 325 completed cars would be sent away from the works that day, the raw material entering at one end of the vast shops and the finished products issuing at the other end. Under such conditions it is absolutely essential that law and order and system prevail and that each engine be set up and run and tested in the shortest possible space of time consistent with thoroughness.

In order to facilitate the work, the test house is a long, narrow room with about 100 testing blocks ranged along either side in two long aisles. The modus operandi is much the same in both the Ford and Studebaker plants, a photograph of the Studebaker testing room being reproduced herewith. As the motors come from the final assembly room, they are picked up by an overhead travelling crane and deposited upon the testing blocks. Here, too, the jig system of holding work prevails, and each motor is fastened down securely by four thumbscrews.

As is fairly well known, every new motor is more or less stiff, and it sometimes is more than a one-man job to induce an engine to start and to keep running under its own power. In both the Ford and Studebaker plants the work has been made a four or five horse job, however, and is thereby rendered correspondingly easier. Running the length of the rooms, at the flywheel ends of the testing blocks, there is a narrow-gauge railway track which mounts a small truck carrying a big electric motor, power for the motor being collected from two overhead wires, after the manner that has been perpetuated by the common variety of trolley car. The electric motor is equipped with pulley and a belt and runs continuously. When it becomes necessary to start one of the motors under test, the electric motor is moved adjacent to the testing block, the belt slipped over the flywheel of the engine, and if the engine does not start immediately, it can be "turned over" indefinitely until the proper carburetter adjustment has been made. In fact, all the motors are started with the gasolene turned off, the carburetter adjustment being made while the engine is running under the persuasion of the electric motor. Where a battery system of ignition is used, the ignition wires remain stationary over each engine. In the Ford plant, the four wires which attach to the spark plugs are attached to a small board which is drilled with four holes corresponding to the location of the plugs. The board is then merely slipped over the plugs and the high tension current jumps the short distance between the tops of the plugs and the terminals on the board. In this way the time required to make ready an engine for test is materially shortened. The actual test consists of a run the duration of which is governed by the condition of the engine, as shown by frequent inspections.

Of course, where production is less stupendous and more time is available, more elaborate testing methods can be used, in which connection it may be remarked that there scarcely are two manufacturers whose testing equipment is the same, or who use similar methods. In practically every case, motors first are run for several hours "on the belt"—that is to say, they are set up on a testing block and are run from the overhead shafting by means of a belt over the flywheel. They do not run under their own power, the preliminary "running in" being merely to smooth down bearings and cylinder walls. Afterwards they are set up on testing blocks in the test house and are run for varying lengths of time under their own power. In some cases they are run under load while in other cases they are not.

At the Peerless plant, in Cleveland, for instance, the engines are run several hours light and then are run eight or ten hours under a water brake load. Afterward ,they are transferred to another testing block and a horsepower reading taken with a Tracy fan dynamometer. At the Winton plant an entirely different method is used. As in the other case, the motors first are run "on the belt." Then they are placed directly in the chassis which is to be their final resting place and run for hours light. Finally the whole chassis is removed to the testing apparatus, which consists of an electric dynamometer. The dynamometer is connected to the engine through the intermediary of the propeller shaft and the change gear mechanism, and in this way practically the whole car is tested at once, speeds being shifted occasionally in order to "run in" the gears as well.

A somewhat similar method of engine testing is used at the Stearns plant in putting the final touches on the Knight engines with which the pleasure cars are equipped. The engines first are "run in on the belt," after which they are mounted in chassis and are to all intents and purposes ready for the road test. Instead of being sent out on the road, however, the cars are run into a courtyard and backed up to a high wall. The rear of the chassis then is hung up by means of steel rods and long vertical belts are slipped over both rear wheels. The belts turn big wooden fans built on platforms arranged on the side of the building. The test therefore includes the engine and the change speed mechanism and goes a little further than the Winton test in that the differential mechanism also is included. This portion of Winton cars, and, in fact, all other cars, is tested, of course, when the cars are sent out on the road for the final abuse to which the corps of road testers subject them.

At both the Packard and Peerless plants the running-in process is carried out on specially constructed tracks which encircle the works. On these tracks the cars are run until they meet the approval of the final inspector, no matter whether the distance be 100 or 1,000 miles. Afterward they are sent over the roads as a matter of course. The Packard track is slightly smaller than the Peerless track and encloses an athletic field equipped for baseball and other field sports, even to a commodius grandstand.

Vent Hole That Should Be Screened.

Though it is fairly well known that much of the so-called carbon that collects in engine cylinders to cause loss of power and otherwise evidence its unwelcome presence enters by way of the air intake in the form of common road dust, it may not be so well known that a considerable quantity of dust may also find its way into the float chamber through the minute hole which is placed there to prevent a vacuum being formed over the fuel. It is impossible to plug the hole up, of course, without interfering with the proper operation of the carburetter, but it is possible to cover the hole with a small piece of fine wire gauze. Air then will be admitted to overcome the vacuum which otherwise would be formed, and the greater portion of the dust and road dirt, at least, will be excluded. It is needless to explain that if the dirt is permitted to find its way into the float chamber it will clog the needle valve or the fuel line and will cause undue wear in the float mechanism.

MEANING THAT HIDES IN CURVES AND DIAGRAMS

How Sinuous Lines Are Made to Impart Accurate Information When Understood—Pressure, Vacuum and Distance Measured and Recorded by Mechanical Fingers—Disentangling Facts from Curlicues That Befuddle the Brain of the Unknowing.

"It looks like the path of a Kansas cyclone," said the man who was not an engineer. "That other one looks like the baby's first picture of a bird What good are they?"

"Why, they're indicator diagrams," said the Designing Engineer, as if that settled the matter for good and all.

"Oh!" mused the untechnical one, dubiously. "I thought so; I've seen things like it in high-brow dissertations and sich like. But they always are Chinese puzzles to me."

"Chinese puzzles!" exclaimed the D. E., in a scandalized voice. "Why, these are verbatim reports of the proceedings inside the cylinders of gasolene engines, translated into English. Look at this one; you can see exactly where the charge was ignited—late in the stroke—and you can see what happened afterwards in the high pressure at the end of the stroke and the sharp dip to the atmospheric line——"

"Easy, easy! I'll take your word for it. I know you fellows are expert decipherers of cryptograms and readers of hieroglyphics; but I want to know if any human being with only the normal equipment of brains can make head or tail of one of those—those—birds?"

"Certainly," replied the D. E. "And if you're 'game,' come around at lunch time and I'll give you a little course on curves that will make you a little more respectful to curves in general and indicator diagrams in particular, and show you interesting things where you thought there were none."

The man who was not an engineer was "game" and he went, and for all his flippancy he was interested and enlightened. It is a rather strange fact that of all the men who are interested—vitally interested—in various ramifications of business that are intimately connected with the gasolene motor, very few outside of the designing departments know how to get any information from an indicator diagram. Even among the men in the factories such knowledge is comparatively rare, and as for the sales department, one might as well look for the proverbial sewing tool in a pile of cow-fodder as for enlightenment on indicator diagrams from any of the members of a sales force. And yet the subject is not by any means of unfathomable depth. Of course, it is like almost any other detail of engineering in that the greater one's familiarity with mechanics and engineering the more it is possible to extract from a diagram; but the principles that govern the indicator "card" and its interpretation are sufficiently simple for the comprehension of almost anyone.

The principle upon which a pressure curve is constructed—incidentally, a curve, in engineering parlance, may be a perfectly straight line—is illustrated, in its simplest form, in Fig. 1. A strip of paper, with lines ruled horizontally, is made to move horizontally at a uniform rate of speed.

FIG. 1—SIMPLE PRESSURE CURVE

The ruled lines are numbered, the figures standing for, say, pressure. A pencil point rests on the paper; by means which are immaterial in the present instance the pencil point is made to move upward with increase of pressure, and downward with decrease of pressure. When there is no pressure it rests on the bottom line, which, therefore, is called the atmospheric line, or the line where only atmospheric pressure exists. If the paper moves along when

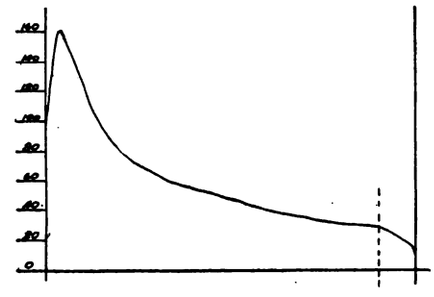

FIG. 2—EXPANSION

there is no pressure to move the pencil, a straight mark will be traced along the atmospheric line, but the instant pressure commences, the pencil will commence to rise, tracing the tell-tale line as it goes. Obviously, the paper must be so ruled, with reference to the work it is expected to record, that the values indicated will be correct. This also is a detail that must be taken for granted. If the pressure rises at a uniform rate, the pencil will trace a straight line that will slant upward at an angle directly proportioned to the rate of pressure increase. Should the pressure rise instantaneously, the line of course would go straight up. If the pressure rises and falls an undulating line will indicate the fluctuations.

Such a curve is an extremely simple one, and can be followed without the slightest difficulty; it is natural and comprehensible that the recording line should rise when the pressure rises, and fall when the pressure falls. And, to carry the matter a step further, it is equally natural that should a partial vacuum occur instead of pressure—or, more correctly speaking, if the atmospheric pressure should be reduced—the recording line should drop below the atmospheric line. But when a second factor is introduced into the production of a curve it becomes a little less simple.

To get back to the indicator diagram, let it be assumed that it is desired to make a curve of the pressure during the power stroke of a motor, ignoring the rest of the cycle for the present. The length of the diagram will represent the length of the stroke of the motor. Fig. 2 shows such a curve. For the sake of simplicity, it will be assumed that the paper moves forward while the piston makes its power stroke, the motion of the paper and of the piston beginning and ending exactly at the same instant. Just after the beginning of the stroke, as a rule, the pressure in the cylinder will be maximum, for the charge has been compressed and ignited and the sudden expansion, or explosion, sends the pressure skyrocketing for an instant. Thus, when the stroke begins the pencil will be high up in the diagram, indicating high pressure at the very beginning of the stroke. The pressure line drops away rapidly, however, in the early part of the stroke, because the difference in temperature between the burning gases and the cylinder walls is so great that a great deal of heat is transferred to the walls and thence to the jacket water, and as the temperature decreases the pressure is correspondingly reduced. At the same time, the piston begins its stroke and the space the gases must fill is increased, which further decreases pressure. As the difference in temperature decreases the drop in pressure becomes less marked, and the curve becomes flatter—a tendency that is increased by the fact that while the outwardly moving piston constantly increases the volume of space to be filled, and so tends to lower the pressure, the ratio of volume increase becomes less and less as the piston moves

Digitized by Google

further from the cylinder head. To illustrate this point: Suppose there is a clearance of one inch between piston and cylinder head at the end of the compression stroke. When the piston has moved out one inch the volume of space will be doubled, or increased 100 per cent., but the second inch that the piston moves will increase the volume only 50 per cent., the third inch 33 1-3 per cent., and so on, in a constantly decreasing ratio. After the piston passes mid-stroke and commences to slow down as it approaches the lower dead center, the pressure drops still less.

If this diagram is divided or scaled off horizontally, so that the divisions represent pounds pressure, it will be an easy matter to ascertain just what pressure was attained at any point in the stroke; and with the instruments used for making such diagrams it is known to a nicety just what pressure is required to produce a curve of a given height. Thus it is by no means difficult to scale off a diagram after it has been traced.

Toward the end or "toe" of the expansion

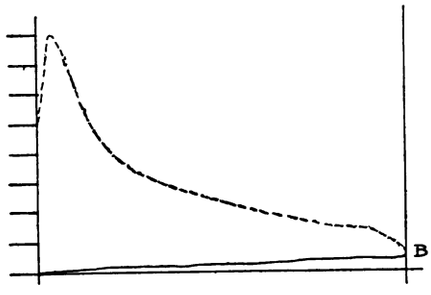

FIG. 3—EXHAUST

curve there is an abrupt downward tendency of the line, showing that something has occurred to cause the pressure to drop, for only a drop in pressure can cause a drop in the line. This is caused by the opening of the exhaust valve. It is found, by measurement, that the point where the valve commenced to open is one-tenth, say, of the length of the stroke. As the stroke involves half a revolution of the crankshaft, which means rotation through 180 degrees, or half a circle, the exhaust valve opens one-tenth of the 180 degrees, or 18 degrees, before the end of the stroke. The curve continues, with a sharp downward trend, to the end of the diagram—that is, to the end of the stroke. As yet, however, the pressure has not reached zero, though the stroke has been finished and the exhaust valve is wide open; therefore it is clear that there still was considerable pressure as the piston stopped at the dead center—35 pounds, according to the scale. This completes the expansion stroke, for the line having reached the end of its movement, must turn back, just as the piston must. The next stroke is the exhaust stroke, and it is shown in Fig. 3. The expansion stroke, already followed, shows in dotted lines.

While the piston was on dead center, B, with the exhaust valve open, considerable gas was exhausted and consequently there was quite a drop in pressure before the piston had fairly started on the upward or exhaust stroke. The speed of the piston, pushing the gases ahead of it, kept them fairly well packed, so to speak, and prevented the continuation of the rapid pressure drop. Nevertheless the pressure becomes lower and lower, approaching nearer and nearer to the atmospheric line, until at the end of the exhaust stroke, there is no pressure at all. Evidently, then, the exhaust valve and passages are of sufficient size. Had they been too small, so as to choke the egress of the gas, the piston would have pushed the gases faster than they were able to escape, and consequently the pressure would have piled up and the exhaust line would have been kept higher above the atmospheric line; in an extreme case there might even have been a sort of

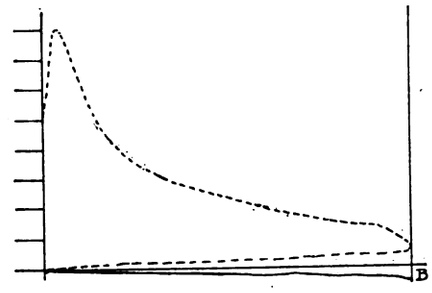

FIG. 4—INTAKE

hump in the line at mid-stroke, indicating that at the point where the piston was moving fastest it had pushed so hard against the choked gases as to cause an actual rise of pressure, which, of course, would be what commonly is called back pressure and means serious loss of power. In the normal diagram, however, the back pressure is not excessive, and at the end of the stroke there is no pressure. This ends the exhaust stroke; the exhaust valve closes and the intake valve opens, and the suction stroke begins.

Fig. 4 is different from all the preceding figures because it deals with partial vacuum instead of pressure above atmosphere; it represents the suction stroke. If the intake valve could be made as large as the head of the cylinder there could be no vacuum at any speed an engine could attain, and the suction curve would follow along the line of atmospheric pressure. Such a valve is impracticable, however, and unnecessary, and with a valve of ordinary dimensions the vacuum formed is very slight, as the small drop of the line indicates. Just as a small valve would produce back pressure on the exhaust stroke, so a small intake valve would produce a retarding effect on the piston on the intake stroke, and it would be indicated by a drop in the line instead of the rise or "hump" that would indicate pressure. At the end of the stroke B the cylinder is filled with gas, and, as the line shows but a slight drop at the end of the stroke, it is evident that there was little vacuum when the piston arrived at the dead center, but that the cylinder was filled with gas at slightly less than atmospheric pressure.

The compression stroke shown in Fig. 5, starts from the atmospheric line, where the intake stroke finished. The pressure rises, as the piston decreases the space in which the charge is imprisoned by the closed valves, and forms a curve that is similar to the expansion curve in that it rises at first slowly and then more and more rapidly, as the space in which it is confined decreases in the same ratio as the increase of volume in the expansion stroke. If the curve were allowed to continue it would sweep up to about 85 pounds pressure at the end of the stroke; but it is not. When the pressure has reached about 70 pounds and the stroke is within a few degrees of its end, the pressure suddenly shoots up, and while the piston is standing still for a brief instant at the top dead center, the pressure continues to rise, going straight up. There is, of course, only one thing that could cause such a sudden and violent and practically instantaneous rise

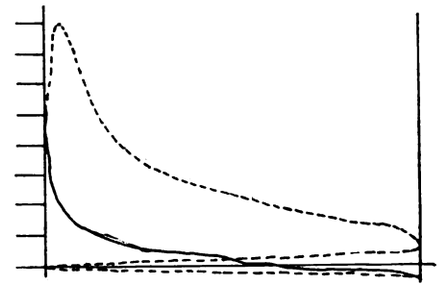

FIG. 5—COMPRESSION

in pressure—the ignition and expansion of the charge. The point where the gradually sweeping curve turned suddenly upward is where the spark occurred—a few degrees before the termination of the stroke, or a little advanced. The pressure was maximum just after the piston started on its power stroke. This completes the diagram.

Fig. 6 is a normal diagram and is a practically exact copy of one taken from a very good small motor running at about 1,300 R. P. M. It is, of course, necessary that one should be familiar with the mechanical sequences in a gasolene motor if the indicator diagram is to have any meaning; but for one who understood nothing about the motor the diagram would hold no interest anyway.

The diagram that has been used for illustration is smooth and symmetrical and quite easily read. If it is thoroughly understood, however, the "Kansas cyclone" variety of diagram becomes less terrifying, and acquires a meaning. Fig. 7, for instance, though not violently erratic, shows some abnormalities. It will be noticed that there is an absence of very high pressure at the commencement of the power stroke, but the pressure does not drop until the piston has traveled about a fourth of its stroke.

Digitized by Google

the pressure keeping up notwithstanding the increase in volume of the space in the cylinder. Looking for a reason, the curve is traced back a little and there is no evidence of the sudden upward shoot that indicates rise of pressure due to ignition before the end of the stroke; the pressure rises, however, while the piston is on the dead center, so the charge must have been ignited at the end of the stroke—in other words, ignition was somewhat retarded. Maximum pressure was reached just after the piston started its outward travel. It might be thought that the maintenance of such a high pressure for such a considerable proportion of the stroke would result in high power. By following the curve, however, this idea vanishes, for when the exhaust valve commences to open near the end of the stroke a great deal of the pressure still is there, as is indicated by the height of the pressure line above the atmospheric line. All through the exhaust stroke there is considerable pressure on the piston, which means that the engine is doing extra work in pushing out gases at

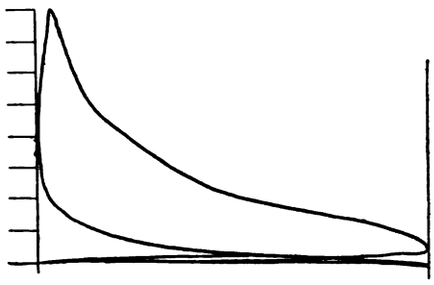

FIG. 6—TYPICAL DIAGRAM

high pressure; moreover, the gases are abnormally hot because there has not been time for complete combustion, and this indicates clearly the way in which retarded ignition overheats a motor, the pressure and temperature, which go together, being abnormally high throughout the stroke, and the exhaust being very hot indeed.

Following the steep exhaust curve, it will be noticed that it never reaches the atmospheric line, showing that there was back pressure throughout the exhaust stroke. Moreover, at some distance from the end of the stroke there is a sudden rise in pressure. The natural thought would be that the exhaust valve closed too soon, and the trapped gases caused the pressure to go up. The objection to this theory is that the pressure does not continue to rise clear to the end of the stroke, as it would if the gas was trapped by closed valves; moreover, if the exhaust valve closed very early it would also open very early, and there is nothing in the expansion stroke curve to indicate that the exhaust valve opened too soon. Here is where a knowledge of the conditions under which the diagram was made is essential. It happens that this particular diagram was made from a multiple cylinder motor in which the exhaust strokes overlapped—that is, the exhaust stroke of one cylinder began before the exhaust of another was completed. With the charge burning slowly and the exhaust issuing from the valves at abnormally high pressure, there was a great deal of pressure in the manifold. So when the diagram shown in Fig. 7 was approaching the end of the exhaust stroke, another cylinder began to exhaust,. and the pressure in the manifold backed in through the open exhaust valve and raised the pressure, as shown by the rising exhaust line.

Fig. 8 is a rather curious diagram, showing very clearly the effect of late ignition, together with a rather slow-burning mixture. The compression curve shows that the compression of the charge was carried to the end of the stroke without interruption; there is no break in the smooth sweep of the line. Ignition did not occur until just as the piston commenced its outward stroke, and, as the mixture was a poor one, it fired somewhat slowly and the pressure actually dropped somewhat during the

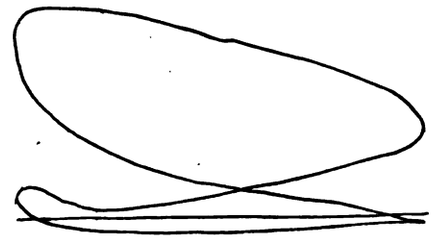

FIG. 7—ABNORMAL CARD

early part of the stroke. Once well ignited, however, the pressure went up in a high, swelling curve; the pressure remained very high up to the opening of the exhaust valve. There was a clear, free exhaust, for the pressure drops quickly after the opening of the exhaust valve. There is a curious feature of this diagram that not infrequently is observed.

The exhaust pressure not only falls to zero, but it goes further, and a partial vacuum is formed before the end of the exhaust stroke, as the diagram shows, for at the point where the exhaust curve reaches the end of the stroke it indicates a negative pressure, or vacuum. This is due to the inertia of the gases which passed out at very high velocity earlier in the stroke having a tendency to draw after them the slower-moving tail-end of the cylinderful. Naturally this results in a scavenging action that leaves comparatively little burned gas in the cylinder, and the inspiration of a very full charge is facilitated. In the case of a multi-cylinder engine the exhaust from other cylinders sometimes assists in bringing about this effect in some cylinders, while having the opposite effect on others, as indicated by the diagram in Fig. 7.

If an engine is turned over by external power and an indicator diagram taken from it, the curves will be quite different from those made while running under its own power. The suction or intake stroke will make the same line, as will also the compression stroke; but in place of the power stroke, during which the charge of gas burns and increases the pressure upon the piston, there is a simple expansion of the air that has been compressed. As the compressed air merely returns to its original state, passing through the same stages as in the compression stroke, only in the reverse order, the expansion curve will be a duplicate of the compression curve if there is no loss of compression. If there are leaky valves, or if air can blow past the piston rings. the expansion line will, of course, drop below the compression curve, because the pressure will be less at any given point in the stroke. At the end of the expansion stroke, at which point the curve will touch the atmospheric line again, the exhaust valve will open and the exhaust line will, if the valve and passages are free, follow almost exactly along the atmospheric line, showing a little pressure, perhaps, if the engine is being turned over very rapidly.

Fig. 8 is a genuine case of "Kansas cyclone," but really is not nearly as bad as it looks. The secret of it is that it consists of two superposed diagrams taken from the same cylinder under different conditions. The upper line indicates late ignition and

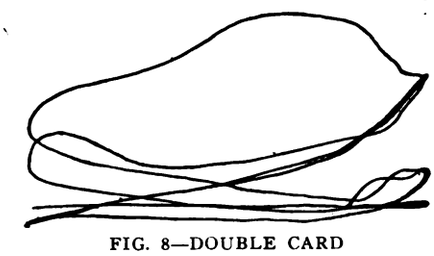

FIG. 8—DOUBLE CARD

slow burning of the charge, with high pressure throughout the stroke and high-pressure, hot exhaust. The sharp rises at the end of the exhaust stroke indicate early closing exhaust valve. The second line from the top shows that a charge of very weak or else over-rich gas was taken in, for it burned excessively slowly, the line following the compression line for some distance and then, as the flame began to gain a little headway, the pressure rose, though very feebly, until it reached its maximum just before the opening of the exhaust valve. The sudden drop at the end of the stroke, when the valve opened is clearly shown. Had the charge failed to ignite at all, there would have been nothing on the diagram to show it, for the expansion line would have followed the compression line back to zero, as already described. Even the reason for the faulty burning of the charge may be "doped out" from this freaky looking diagram. Ignition was very late, and the slow-burning charge was still hot and under high pressure when the exhaust valve opened, so that there was considerable back pressure. At the end of the exhaust stroke the early closing of the exhaust valve trapped quite a considerable volume of this dead gas, and it was, of course, carried over until the next intake stroke, when it mingled with

Digitized by Google

the incoming charge and diluted it; probably the mixture was none too good, anyway, judging from its slow combustion, as shown by the upper expansion line.

As has been said, it is important in reading a diagram that something should be known of the conditions under which it was made, if all the information it contains is to be extracted. But in a general way, an indicator diagram will tell its story even if nothing is known of the conditions. It is possible so to juggle the conditions as to make a freak diagram that is absolutely undecipherable without the key. It is possible to alter the adjustments of the indicator so that certain parts of the diagram will be exaggerated, or magnified, for the purpose of studying them more closely. This often is done in the case of the curves indicating the intake stroke and of the ends of exhaust stroke curves. But an ordinary, normally proportioned diagram is by no means a puzzle, and a little study of the curves, always mentally associating each line with the piston stroke it represents, will result in an understanding of these useful sources of information that cannot fail to be of interest, if not of actual value.

Graphite That Serves as a Foundation.

When a motor has been taken down for a thorough cleaning it is a good plan before putting it together to rub into the dry surfaces of the cylinder walls, pistons and rings and the main connecting rod and piston pin bearings — in fact, all points where there is friction—graphite mixed with cylinder oil to the consistency of a rather thin paste. If the lubricant is applied with a swab on the end of a stick it will be less disagreeable to handle. It should be vigorously rubbed in and then most of it wiped off. The theory is that the graphite lays a good foundation for subsequent lubrication and ensures a good start without danger of early cutting or scoring of bearing surfaces.

Tongue Test for Low Tension Current.

If there is any doubt as to whether there is current flowing through the low-tension wiring of an ignition circuit it can be set at rest by placing the two terminals on the tongue, not touching each other. If there is current flowing there will be a sharp, sour taste, but if there is no current there will be no taste; the stronger the current the more sharp the taste. Obviously this test is exclusively for very low tensions, and to try it on strong current circuits would cause decidedly unpleasant effects in the tasting apparatus.

Using Magnet to Test Tool Steel.

One method of ascertaining the correct heat for tool steel that is to be hardened is to use an ordinary permanent magnet. The steel becomes non-magnetic just before reaching the proper temperature for quenching, and therefore should be very slightly heated after it ceases to show attraction for the magnet.

BACK-FIRING RENDERED HARMLESS

How Fires from "Sneezing" Carburetters Can Be Prevented—Removing Gasolene Drippings Out of Harm's Way.

A blaze started by the back-firing of the motor may or may not result in serious damage to the car, according to the quantity of fuel there happens to be for the flames to feed upon. If there is no way for gasolene drippings from the carburetter to escape, the chances are favorable to a more or less costly little fire, while if

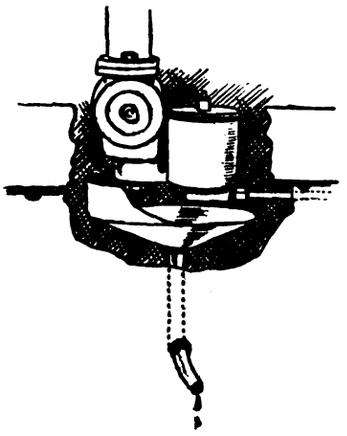

FIG. 1—SHOWING WIND SHIELD

there is no place where gasolene can accumulate there can be only a few drops to burn, and the fire will quickly die out. It is true that the pans of most cars are provided with drainage openings, but this hardly is enough, for if there is much flooding of the carburetter there will be a sufficient quantity of gasolene in the pan to

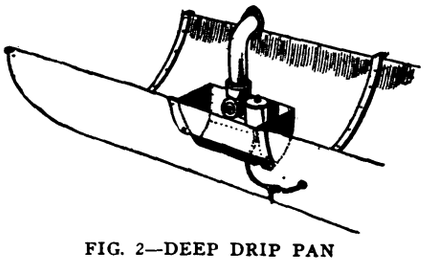

FIG. 2—DEEP DRIP PAN

make quite a fire, and the oil that is pretty sure to cover the bottom of the pan will help things along considerably.

The proper way is to arrange to drain all drippings directly away from the carburetter by building a little drip pan for the carburetter and running a drain pipe, so that the liquid may fall on the ground, out of harm's way. As there is a strong draught of air over the carburetter when the motor is running, the dripping gasolene will be blown back and away from the carburetter drip pan if some provision is not made to prevent it. In Fig. 1 there is a shield at the front for this purpose, while in Fig. 2 the carburetter is partly enclosed by the pan. The illustrations, from "Autocar," are self-explanatory, and show two methods that may be used; but they will not do for all cars, of course, owing to variations in construction details. However, the idea is well illustrated. In Fig. 2 there is a slot in the bottom of the pan which serves a double purpose; it is the outlet for the dripping fuel, and it provides an opening through which the gasolene pipe passes to the carburetter.

A good plan that sometimes can be carried out is to cut a hole through the main pan directly under the carburetter, and from this run a sort of box that will partly enclose the carburetter. If the carburetter floods the gasolene will simply drip through the hole and will be prevented from finding its way into the main pan by the boxing.

Figures Showing How Horse Isn't "Going."

Despite the enormous increase in the use of automobiles and the repeated utterance of the cry "The horse must go," official statistics, compiled by the Agricultural Department at Washington, tend to prove that while the horse may be "going," his pace is not fast enough to cause undue concern. According to the tables that are printed in the department's 18th annual year book, there still are no less than 23,778,481 horses in the United States, not including the Philippine Islands; Canada is next, though far behind, with a total equine population of 2,303,725; the total of Central America, 27,873,248; South America, 9,155,425; Austria-Hungary, 4,196,634; European Russia, 23,548,000; United Kingdom, 2,253,418, bringing the total of Europe to 43,502,876. On January 1, 1867, the number of horses on farms in the United States was 5,401,000; price per head, $59.05; total value, $318,924,000. On January 1, 1912, the 20,509,000 horses were valued at $105.94 per head; total farm value, $2,172,694,000. There are 609,000 horses reported on farms in the State of New York, which is in excess of any other North Atlantic State. Illinois, Iowa, Missouri, Nebraska, Kansas and Texas each have over 1,000,000. Despite the enormous "home production" of horses, there were imported into the United States during 1911 nearly 10,000 animals at an average price of $280.63. The number exported, however, exceeded this number by upward of 15,000.

Rosin that Facilitates Bending of Tubes.

Rosin makes a very good filling for brass or copper tubes which are to be bent, and prevents the formation of kinks and dents without necessitating that the ends of the tube be plugged. It, however, should not be used on pipes which are to be used to carry fuel to the motor, because it is slightly soluble in gasolene and is likely to cause carburetter trouble.

A bearing that is subjected to considerable heat will require more lubrication than one that runs in a cool place, as the heat tends to drive off the oil and leave the frictional surfaces dry and liable to cut.

MUST STOP WHEN STREET CARS STOP

New York's Proposed New Ordinance Near to Passage Despite Impractical Requirement—Reforms Recommended.

Although it contains a provision which, if enforced, would make automobile travel on Broadway—or any other busy street having trolley service—almost an impossibility, the so-called Folks ordinance for the regulation of automobile traffic in New York City seems fair on its way to passage by the Board of Aldermen. When it came up for consideration on Tuesday last it was referred back to the committee on a technicality.

The particular clause in the proposed ordinance which would likely serve to attach unpopularity and impracticability to the measure is a section which, among other things, requires that when an automobile overtakes or approaches a street car which has stopped to take on or let off passengers the automobile shall stop not less than six feet from the street car and remain stationary until the street car has proceeded.

The aldermen, however, in commenting on the ordinance, declare they are acting for the "greatest good to the greatest number."

The speed limits proposed are 25 miles in outlying and thinly populated sections; 10 miles in turning corners, at bridge approaches and in passing schools on school days between 8 A. M. and 4 P. M.; 15 miles in crowded streets, and 18 miles on Broadway and Amsterdam avenue north of 72d street, Coney Island Boulevard and Eastern Parkway, Brooklyn. Proposed penalties are: First conviction, fine of $25 to $100 or fine and 15 days; second conviction, double the first penalty; third conviction within six months, $100 and 30 days.

Alderman Ralph Folks, chairman of the special automobile speed regulation committee appointed by the Board of Aldermen to investigate and draft the ordinance, in submitting his creation made numerous suggestions based upon information gained by the committee in driving automobiles through congested thoroughfares and less crowded streets at various speeds, in ascertaining the efficiency of brakes and the distance required to stop at different speeds and in a study of conditions under which accidents most frequently occur. What, if made a law, would place owners who drive on the same plane as chauffeurs was the suggestion that the owners, also, be licensed to drive, the committee being able to find little reason for discrimination. Chairman Folks also urged the vesting in police magistrates of the power to revoke licenses, instead of centralizing this power in the Secretary of State, and that the identification of drivers of cars, with any previous offenses against the speed law, be a matter of police record he would have filed at police headquarters a card bearing license number, address, signature and photograph of the driver. More motorcycle policemen were urged as a means of coping with present conditions, and a right enforcement of the tail lamp regulation was recommended as an aid in identifying cars at night. Referring to the part pedestrians play in causing accidents, the report says:

"While pedestrians have many just causes for complaint, they are also responsible in many cases for their own injuries, and unnecessarily annoy the drivers. According to the records of the police department, some 800 accidents out of 2,500 occurred in the middle of the block or remote from corners. Vehicles should be entitled to free and unobstructed passage of the highways aside from street crossings."

1913 Refinements That Date Far Back.

Of the comparative youth of the motor car industry there can be no question; as compared with the steam engine, the railroad, the telegraph and even the telephone it is a veritable mushroom, so far as rapidity of growth is concerned, though anything but mushroom-like in its solidity. Quick as the mechanical development has been, however, it is rather interesting to notice that new ideas and new developments usually are revivals or amplifications of much older attempts along the same lines.

For instance, in 1899 the old Automobile Company of America quite nonchalantly asserted that its new models—meaning the cars for 1900—would be equipped with automatic starters. Incidentally, the motors in question had three cylinders and were rated at as much as 10 horsepower. During that period of the development of the automobile the wire wheel was very much in evidence—in fact, they were the rule. Winton and Packard cars had wire wheels; the latter at that time was built by the Ohio Automobile Co., of Warren, O.; so did the Knox, which then had only three wheels; the Stanley steamer, and all the other steamers, which were then very much in evidence; the Peerless, which was a diminutive "motorette" with a little crank to steer with; the Locomobile, then a "tea-kettle"; the Elmore, which was a two-cycle machine but used piston-opened ports instead of the distributing valve and two-diameter cylinder now employed, and many others, most of them having names long ago forgotten. Charles E. Duryea, who at that time had not mastered the art of simplified "speling," was doing most other things in his own original way, including the employment of three-wheeled chassis and one-hand control, and was having no end of trouble convincing the public that he had the right idea, notwithstanding the fact that the Knox people also advocated three wheels. Twelve years or so ago there was a demand, apparently, for a "poor man's car," and one of the machines built to meet the call was the little Autocar, which weighed 500 pounds, cost $500 and had a motor of four horsepower.

NANTUCKET AGAIN IN A FERMENT

Motor Fire Engine Now Excites Motorphobe Colony—Amusing Situation That Exists On the Sleeping Island.

Nantucket, which, as everyone may not know, is in Massachusetts, is again suffering a rush of gasolene to the head. But the other "rushes" were quite unlike this one. In the others the inhabitants of the island united against the automobile and the automobilists as invaders. And they have been so successful that it is set down in the statutes that the general automobile law does not affect the rules of Nantucket, which rules exclude motor vehicles during the summer months. But the present trouble is an internal affair, a struggle between the progressives and reactionaries, and the columns of the local paper are filled with letters to the editor in which opinions are expressed as to whether motor cars should be allowed on the island.

The cause of it all is the progressiveness of the fire wards—as they call firemen in Nantucket—in buying an automobile chemical truck to strengthen the fire department. There was a lot of discussion before so radical a step was taken, but at the annual town meeting early in the Spring an appropriation of $5,900 was put through and the truck was bought and delivered in time so that it could be run off the wharf before the bars were raised against motor vehicles on June 15.

The automobile was duly installed in its house and a chauffeur engaged. But when the fire wards began to take the machine out to "exercise" it trouble began. They held that it was necessary to run the machine every day to keep it in condition so that it could respond promptly to alarms. It became rumored that the firewards were taking joy rides over the state highway to Siasconset, and that other people were being taken along. Something of this sort apparently happened, for the automobile germ got a foothold and soon developed into a formidable party in favor, not only of "exercising" the fire truck, but even of throwing open the island to all automobiles.

The discussion has run high, some holding that the fire wards did not need to "exercise" the machine, and that if they did the tuning up process could be accomplished just as well by jacking up the wheels and running the motor in the fire house, as by running the machine about the streets, to the consternation of the inhabitants and the horses—for Nantucket horses are traditionally afraid of automobiles in summer, though the Boston Transcript meanly insinuates that some of them that come down from New Bedford and elsewhere in the spring never show signs of fear until they reach the island.

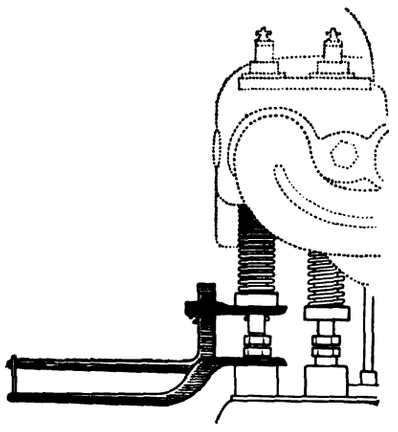
It was agreed that the automobile chem-

Digitized by Google

ical might be "exercised" between 7.30 and 8.30 in the morning, this time being satisfactory to the livery stable keepers, though the arrangement has caused a protest from people who say their morning sleep is broken. Still, that is the time the machine may be seen on the streets, not every morning, but whenever the fire wards consider it necessary to keep it in proper trim to respond to alarms.

But great have been the changes since the automobile chemical arrived. Already the ancient offices of "alarmists" and "keeper of the town's powder" have been discontinued, all these office holders having lost their positions on the first of July. There used to be a "watchman" whose station was in the tower and whose duty it was to be on the lookout for fires and give the alarm, which the "alarmists" transmitted. A fire alarm system was installed and the "watchman" lost his position. But the "alarmists" and the "keeper of the town's powder" have continued until now.

One of the early calls for the automobile chemical resulted in a great disappointment, for the machine did not show up with the speed that was expected. The reason was soon found to be that the man who ran it was asleep in his house some distance away when the alarm was run in, and it took him some time to get to the fire house and get the machine in operation. This caused the fire wards to decide to post the driver of the automobile chemical in its house, and since then the machine has done great work in fighting chimney fires and other incipient conflagrations. It has even won some friends because it has put out fires without arousing the entire community, which was the old custom.



The era of progress has advanced so far that the driver of the automobile has put up a wireless station on the engine house to catch the government time every day for the benefit of the townspeople. There is talk of having a chief of the fire department, and it has been said that the record of the island of never having had a fire since 1846 that has spread beyond the building in which it originated is not due to efficiency of the department, but just to luck. Some go so far as to say that had Nantucket owned an automobile chemical in 1846 there would have been no "great fire" of that year.

But the talk started by the arrival of the automobile chemical and by the alleged joy rides that followed has spread from its original subject and now the whole question of opening up the island to automobiles is being vigorously discussed. There is a war of words, and every time the new chemical goes out it seems to be strengthening the side of the progressives. They are now suggesting that Nantucket horses would get over being frightened at automobiles if they had a chance to see them, and that, furthermore, the livery stable men could make more money carrying people about in automobiles than they do with their surrey hitches that have for years been the accepted mode of transportation, barring the railroad.

But the conservatives are not idle and they are putting up stiff arguments why automobiles should be kept off the island. They say it is for rest and quiet that people come there, and they do not want the things they have at home. People come to Nantucket from all over the country to get away from noise and street dangers, and if automobiles were introduced it would spoil the place and its summer business. Furthermore, the narrow and crooked town streets and the sandy country roads are arguments as strong now as they ever were against the introduction of automobiles.

Tool that Aids Valve Spring Removal.

One of the most disagreeable of the little jobs connected with the ordinary work on a gasolene motor is the removal and

replacement of valve springs, especially if they are of considerable stiffness, as is the case in big motors. Various makeshift methods of prying up the springs are employed, so that the key can be withdrawn and the valve freed from the spring action, but at best they are a nuisance and often result in pinched fingers, if nothing more serious. One of the many tools designed to facilitate this work, and one that has advantages peculiar to itself, is the Cummings plier, made by the Wright Wrench & Forging Co., of Canton, O., for the Cummings Plier Co., of the same place.

As the accompanying illustration shows, the tool is extremely simple and easily handled, and as its name indicates, it resembles somewhat a big pair of pliers, except that the jaws are forced apart when in service instead of closing. Both jaws are forked; one is rested on the top of the valve lifter guide and the other, which is adjustable as to its distance from the lower jaw, is placed under the spring or between the coils, when pressure on the handles compresses the spring and permits the removal of the key. The process, of course, is reversed in replacing a valve spring. The tool is drop forged from steel and is case-hardened; its weight is 14 ounces.

Where Temperature Control Is Essential.

In the pouring of molten metals for making castings, as well as in the hardening, tempering and other heat treatment of steels, the regulation of temperature is of the most vital importance and upon it may, and usually does, depend the success of the work in hand. For instance, when making light, thin brass castings, it is necessary to bring the molten metal to a much higher temperature than that which is required merely to melt it; it must be made sufficiently fluid to run easily into the intricacies and small places left by the pattern. But the metal must be poured immediately the requisite temperature is attained; otherwise the excessive heat will drive off the softer ingredients—tin, lead and zinc—in the form of vapor, and the resulting castings will be far from perfect.

On the other hand, for making heavy castings the employment of very high temperatures will result in excessive shrinkage, so that the shrinkage allowance made by the pattern-maker will be exceeded—in other words, the castings will be under size. The more highly developed alloy steels require the most careful handling as to temperature, and an error in the heating may very easily cause the metal to deteriorate so that it will be no better than common cheap steel. Ordinary tool steel is quite hardy in this respect, comparatively speaking, for if a little overheated its "virtue" often can be restored by working under the hammer at the proper forging temperatures; but once the alloy steel is burned or seriously overheated it is practically ruined, as far as its superiority over common steel is concerned.

Tempering Tools Without Use of Fire.

A machine shop "stunt" that at one time was quite popular as a test of skill consisted in hardening and tempering a screwdriver or other small tool in the finishing process without the use of fire. It was accomplished by doing the last of the rough shaping on an emery wheel, pressing the steel hard against the wheel, so that it was heated red hot by the friction, and then plunging it into water, which, of course, hardened the steel outright. Another heating on the emery wheel tempered the steel, the tempering being checked by a second quenching when the proper color was in evidence. The final grinding was done on a grindstone. The secret of doing this job properly lay in allowing sufficient metal for the rough grinding, so that the requisite heat would be attained just before the blade reached the proper degree of thinness, leaving sufficient stock for the tempering and the finishing grinding.

One Way to Test Heat of Babbit.

Overheating babbit metal when melting it preparatory to pouring bearings is injurious to the quality of the metal and should be carefully avoided. A good rough and ready guide is to thrust a dry pine stick into the melted metal, which should be just hot enough to make the wood smoke, but not hot enough to char it or cause it to flame up.

INEXPENSIVE GASOLENE STILL A POSSIBILITY

Abundance of Motor Fuel to Be Had Through Proper Methods of Distillation—Crude Oil Capable of Yielding Much More Gasolene Than the Refiners Extract From It—Government Experiments in Production and Use of Liquid Gas That Promise Relief.

Although the none too gradual rise in the price of gasolene naturally is attributed by the producers solely to the relation between supply and demand, it reopens the vast field for speculation as to what fuel will take the place of the lighter petroleum products when the supply will have fallen so far short of the demand as to make the utilization of gasolene as a motor fuel prohibitive, and while shale oil, alcohol and other things invariably are suggested, it may be said with positiveness that the possible supply of gasolene is so great that, were the most made of it, little would be heard of "gasolene famines" or sky-high prices.

Commercial gasolene, which is used universally as a motor fuel, is a blend or mixture of three of the lightest distillates which are produced from crude petroleum and represents but 22 per cent. of the volume of the crude oil from which it is produced. The other 88 per cent. is made up as follows: Kerosene, 35 per cent.; distillate or fuel oil, 10 per cent.; lubricating and cylinder oils, 15 per cent.; vaselene, residuum and loss, 18 per cent. It long has been known that the heavier petroleum products, the kerosene and distillate which have chemical formulas more complex than the formula of gasolene, will when heated to the proper temperature and protected from the atmosphere so as to preclude the possibilities of burning, "crack"—that is, split up into two or more products with more simple molecular formulae, lower specific gravities and lower boiling points. The physical properties of these new compounds, when the cracking operation is carried on under proper conditions, are similar to the properties of gasolene and naphtha and their behavior when used as fuel in internal combustion motors is identical with the behavior of gasolene. It naturally follows that, were the process of cracking the heavier oils perfected and practiced, at least 45 per cent. more of the total volume of crude oil distilled would be available as gasolene, or as substances not substantially different from gasolene in behavior.

Upon the way in which the cracking process is carried out, and the constituents of the retort contents, depend the physical properties of the products, so that by adopting certain temperatures and conditions a gas such as Pintsch gas or Blau gas is formed which readily can be liquefied by compressing under reduced temperature. The liquid products can be transported in the same way that carbon dioxide is transported, in pressed steel tanks capable of withstanding heavy pressures. These liquefied gases, although not of the same consistency as gasolene, can readily be used as motor fuel.

A process which should be looked upon as one possessed of great possibilities of future development is that of liquefying the very volatile petroleum products which are contained in natural gas. The commercial possibilities of the latter process are pointed out at great length in a pamphlet entitled "Liquefied Products from Natural Gas: Their Properties and Uses," which recently has been issued by the United States Bureau of Mines. Among other things, this interesting little work says:

"In some of the petroleum fields, particularly in new fields, where the yield of oil and gas is abundant and the methods of handling are necessarily crude, considerable quantities of oil and great quantities of gas are wasted in various ways. In the older fields, where effective methods of handling and storage have been more fully developed, the loss is less.

"Yet in almost all the petroleum fields of the country more or less natural gas has been allowed to escape without restraint, and at some places enormous quantities have been wasted. Even to-day, in practically every field of the country, one can see many gas torches needlessly burning the entire 24 hours.

"Natural gas may be divided into two great classes, (1) a so-called 'dry gas,' known and used for many years as the natural gas of commerce, and (2) a gas containing easily liquefiable vapors, which is known in the vicinity of the oil fields as a 'wet gas.' The latter class forms the basis for the so-called 'natural gasolene' industry.

"By fractionating natural gas either during or after liquefication, four products can be commercially obtained. Roughly, these four products may be described as follows: (1) The gaseous product, the common natural gas of commerce; (2) the semi-liquid product, known as the new 'wild' product, which should be used only as a liquefied gas and should be held in high-pressure steel containers only; (3) the light liquid product, or light gasolene, used for blending with heavy naphthas; and (4) the heavy liquid product, or ordinary high-grade gasolene.

"The liquefaction of natural gas products was early recognized as of possible commercial importance.

"Pasenmeyer and others procured gasolene in commercial quantities near Titusville, Pa., in 1904, by collecting the condensations in the gas mains. The yield of gasolene so obtained was further increased in 1905 by chilling the pipes with cold water, and from 1905 to 1909 the yield was still further increased by the establishment of small, low-pressure, single-stage compressing plants. In the last few years the industry has made remarkable strides.

"Up to the last two years the general practice in the manufacture of liquid natural gas was to make the product by compression of the gas in single-stage compressors operated at a pressure of 150 to 300 pounds per square inch. The one product thus obtained, so-called 'natural gasolene,' was run into a tank and 'weathered.' The weathering consisted in allowing the lighter portions to volatize spontaneously and escape into the open air until such time as the boiling away of the liquid had practically ceased. Thus the process involved a loss of 25 to 50 per cent., or even more. This loss was an absolute waste, not only of power and of cost of operating the engines and compressors but of the product itself.

"The next step in the industry was to pass the waste gases (of which only the small quantity used for power had been utilized) from the single-stage compressor through a higher-stage compressor, thereby getting a second and more volatile product —a 'wilder' liquid—which was run back into the first tank and mixed with the first or heavier condensate. The mixture was then again weathered to a safe degree, whereby it lost the greater part of the more volatile product that had been condensed in the second stage.

"Recently the process has been improved another step, in that the first stage compressor product is run into one tank and handled as ordinary gasolene; the second stage compressor product is run into a second tank and handled as a lighter gasolene, with which the heavy refinery naphthas can be enriched or enlivened.

"The last mentioned method of using the second stage compressor product should receive wide recognition, and a market for the product should develop that would be no mean factor in the industry. Blending in the proportions of, say, 1 part of the product to 4 or 5 parts of the refinery naphthas makes these heavy naphthas more volatile and of greater value as fuel for automobiles; it also greatly increases their general usefulness. The proportions to be used in blending, however, must be determined more definitely by test.

Digitized by Google

"The natural gas of this country frequently contains light products that do not condense in the second-stage compressor, and for which it is practicable and necessary to install three, four, and even higher stage compressors. These light products —true gases at ordinary temperatures and pressures—can be compressed and liquefied, but the liquid gases so obtained must be handled as gases and not as oils. The mistake heretofore made in the 'natural gas gasolene' industry, as some have recognized, has been the attempt to handle the light gaseous products as oils and not as gases.

"The natural gases of the Appalachian oil fields are not the complex mixtures generally reported, but are composed of the paraffin hydrocarbons with carbon dioxide and nitrogen as impurities. The gases that issue under considerable pressure or that are produced in quantities sufficient to justify piping for distant consumption consist principally of methane and ethane, the methane predominating. Small quantities of the higher paraffin hydrocarbons are also believed to be present. Olefin hydrocarbons and carbon monoxide have not been detected in the samples thus far examined by the Bureau of Mines, and oxygen appears to be present only when the sample has been taken in a faulty manner and air has been admitted.

"Natural gases that issue from old wells in which the original rock pressure has diminished contain higher members of the paraffin series, such as propane and butane, in larger quantities, and when a pressure below atmospheric is applied to the wells still larger quantities of the higher paraffins are obtainable. For example, in the oil pool surrounding Tidioute, Pa., a pool that has produced oil and gas for many years, the gas is now drawn from the wells under a pressure of 12 to 13 pounds below that of the atmosphere, and a liquid product is obtained therefrom without the use of artificial pressure or cooling appliances.

"Some natural gases in the United States contain methane only, and such gases are not adapted to the production of gasolene or liquid gas. Gases that contain no paraffin hydrocarbons higher than ethane require a pressure of 600 to 700 pounds to the square inch at 35 degrees C. for the liquefaction of the ethane. At lower temperatures less pressure would be required. Since these high pressures are not used in the commercial plants producing gasolene from natural gas, ethane is not being liquefied in such plants, but a partial solution of the ethane in those paraffins that are liquefied undoubtedly takes place.

"Propane and butane are on the dividing line between gases and liquids and must be handled as such—that is, as heavy gases or as very volatile liquids—and if held must be imprisoned in strong containers only. Pentane, hexane, and heptane are liquids under ordinary conditions and comprise ordinary gasolene.

"The vapors accompanying natural gas are clean and are ready for compression. They are analogous to the manufactured products, but have the great advantage over the latter of being ready made. However, they are at present in a great measure lost to the industries. The vapors should be compressed, as previously stated, but instead of being run into an open tank, or into a closed tank and weathered from it, with a corresponding loss, they should be run into steel containers and held there under compression.

"The multiple-stage compressor may be used for obtaining a number of products, or the single-stage compressor may be used for obtaining one product; then, by allowing this 'wild' product to escape from a common container into a second, a third, and a fourth container, under partial pressures, it may be separated or fractionated into a second, a third, and a fourth product. This compression and later separation or fractionation of a common 'wild' product into several products is, however, a waste of power, as ordinarily the gas should be compressed through several stages directly into its several products.

"Experiments in the production of liquid gas were made at an experimental test plant installed by the authors at the compressing plant of the Penn Gasolene Co., Follansbee, W. Va. The test plant consisted of a small gas engine, a small compressor, cooling coils of ordinary 1-inch iron pipe immersed in a shallow tank for holding the cooling liquid, and a storage tank made of heavy 6-inch steel tubing. Pressures up to 600 pounds were obtained, and with the use of ice and liquefied gas prepared in the adjoining compressing plant, the product was cooled to 2 degrees C. as it entered the storage tank. The crude gas as it came from the wells was subjected to different pressures and temperatures, and the amount of liquid produced was measured. The quantity of crude gas liquefied was obtained from subsequent volatilization of the compressed product. Samples of the liquid material were passed through a small experimental meter to determine the gas yield per gram of liquid. The following table gives the results of these experiments, in which practically complete liquefaction was obtained:

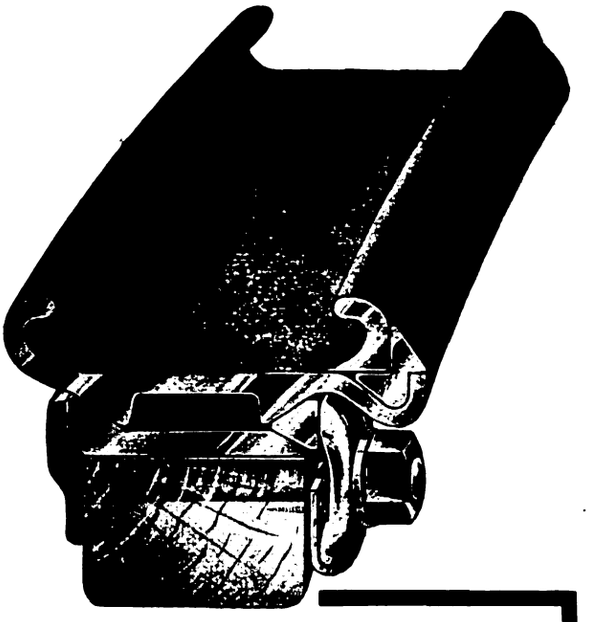
Results of Compression and Cooling Tests of Natural Gas.

Pressure exerted in liquefaction (pounds per square inch).	Temperature of cooling coil at entrance to storage tank. °C.	Volume of gas per gram of liquid. c. c.
415	2.0	600.9
430	4.0	....
506	9.1	....
600	77.5	478.1

"A pressure of 415 pounds at 2° C., of 430 pounds at 4° C., of 506 pounds at 9.1° C., or of 600 pounds at 77.5° C., liquefies practically the total volume of the gas being compressed. Assuming the liquid to be a mixture in which the propane and ethane predominate, 1 gram of liquid will yield 500 to 600 cubic centimeters of gas at 0° C. and 760 millimeters pressure; that is, 1 gallon feet of gas. To determine the feasibility of using for power purposes the gas under discussion, a short test was made with a gas engine. A 10-horsepower two-cycle gas engine provided with a prony brake for absorbing the load, and equipped with the usual electric ignition, was used. The high-pressure cylinder containing the liquid gas was connected through a reducing valve to a small cylinder receiver, capacity about 3 cubic feet, in which a pressure of about 3 inches of mercury was maintained; from this receiver a pipe connection led directly to the engine. No attempt was made to determine accurately the fuel consumption per horsepower-hour, nor to find the compression best adapted for the fuel, the test being made simply to determine its behavior in a commercial type of engine.

"The test was of 30 minutes' duration; full load was easily maintained, and there was no difficulty whatever in keeping the engine up to speed. Throughout the test the engine ran easily, giving no indication of overload; there were no back fires nor preignition. The indications were that the gas would make a satisfactory gas engine fuel. The brake horsepower (10.69) during the run was calculated from the following data:

Avg. revolutions per minute	277.7	
Length of brake arm.....	5.25	feet
Weight of brake arm.....	36.5	pounds
Total weight on scales.....	75	"
Effective weight on scales...	38.5	"



"A cylinder of the liquefied gas was also used for driving a 30-horsepower automobile. A most satisfactory run was made for a number of miles, although no attempt was made to determine the efficiency developed, the only result desired being to demonstrate that the compressed product could be used for automobile propulsion. It was noted that the gas escaping from the container through the regulating valve supplying the engine became chilled and that considerable frost collected over the surface of the valve. The effect would, in general practice, soon freeze the liquid in the valve and clog the pipe entirely. By installing this valve near the engine exhaust the freezing may be prevented.

"The third previously mentioned product of crude natural gas, light high-grade gasolene, is a material that, by co-operation with the refiners of petroleum, can be utilized for blending with the heavy naphthas, thereby, improving the latter and making them more suitable for the propulsion of high-speed automobiles. This use will materially improve the market for the heavy naphthas, and also widen the field of usefulness for the new compression product. The proportions in which the blending should be made to insure some degree of permanency have not yet been established.

"The fourth product from compressing crude natural gas, ordinary gasolene, may be handled in the usual way, and need not be discussed in this paper."

Rims Which Add Value To Any Car

Insurance policies are issued against all kinds of car accidents. Yet no company has dared to write against delays, tire decay or tire wear.

That's the insurance—that's the value added to any car by an equipment of—

"Firestone"

Quick Detachable Demountable Rims

For Every Type of Tire—Clincher or Straight Side

The Value of Tire Protection—Firestone Rims exclusively have "no-split" base. Moisture, dirt, grit nor any other foreign substance can work in to *ruin* casing or tube. *No decay.*

The Value of Easy Demounting—Six clamps loosened, release the Firestone Rim. The simple work of four or five minutes. An ordinary wrench does it. *No delay.*

The Value of Easy Detaching—Because of Firestone exclusive valve sleeve and other refinements, any thin, flat tool inserted under locking ring, slips tire off rim when latter is on wheel if desired. In repeated punctures this feature is most valuable. *No delay.*

The Value of Even Wear—The wedge-shaped clamping ring keeps rim always true—holds tire in perfect circle—presenting rounded surface continuously to the road. *Tire repairs reduced.*

The Value of Long Service—Firestone Rims are designed along simple lines—no delicate adjustments—no rusting together of parts. The rims last indefinitely.

Foremost car manufacturers are adopting Firestone Rims as regular equipment.

Any car manufacturer or dealer can readily recognize the selling power of these features. Get the Book.

1,011,029. Roller Bearing. David Franklin Chambers, Lancaster, Pa., assignor to The Star Ball Retainer Company, Lancaster, Pa., a Corporation of New Jersey. Filed Oct. 15, 1910. Serial No. 587,199.

1. A conical roller bearing comprising a circular series of conical rollers, and a cage consisting of corrugated circular plates having the furrows of the corrugations facing and confining the ends of the rollers, said plates having integral spaced partitions spanning the intervening space at an angle to the axis of the bearing and separating the adjacent rollers throughout the bearing.

1,011,032. Internal Combustion Engine. David H. Coles, Brooklyn, N. Y. Filed Nov. 18, 1909. Serial No. 528,754.

1. In an explosive engine, two coaxial cylinders of unequal diameters comprising a power cylinder and a pump cylinder, a piston having heads of unequal diameters working in said cylinders, the piston head of small diameter being provided with a cooling passage for delivering gas to said power cylinder, a compression chamber having a port adapted to register with said piston cooling passage at or near the end of the power stroke and having a valve controlled port normally closed to said pump cylinder, whereby a charge of gas compressed into said chamber by the pump piston during the compressing stroke is delivered under superatmospheric pressure

through said piston passage into the power cylinder at or near the end of the next power stroke, cooling said piston and filling the power cylinder with a fresh charge of gas.

1,011,091. Resilient Wheel. Johnson A. Suddarth, St. Joseph, Mo. Filed Mar. 25, 1911. Serial No. 616,834.

In a resilient wheel, a rim; a cushion tire on said rim; a plurality of elastic outer spokes having inclined inner end portions formed therewith; a plurality of elastic inner spokes having reversed inclined inner end portions formed therewith, all of said inclined inner end portions of said spokes having notches formed in the edges thereof; a hub provided with holding means by which said inclined spoke portions are held in one annular alinement therein with said outer spokes and said inner spokes thus placed alternately and thereby inclined from said hub outwardly and inwardly respectively; a plurality of outer springs the inner ends of which are substantially secured to to the outer ends of said outer spokes the outer ends of said outer springs being secured to the outer edge portion of said rim; and a plurality of inner springs the inner ends of which are secured to the outer ends of said inner spokes the outer ends of the last mentioned springs being secured to the inner edge portion of said rim.

1,011,171. Spring Wheel. Carl E. Dunham, Maddock, N. D. Filed Mar. 4, 1911. Serial No. 612,264.

In a spring wheel, the combination of an outer member comprising a felly, a tire, an inner rim and spokes, an inner hub member having disks on its ends, covering disks secured to the inner and outer sides of the inner rim and bearing against the ends of the inner hub member and on the outer sides of the first named disks, the said inner hub member being movable eccentrically between said covering disks, and links connecting the inner hub member and the inner rim, each link comprising a pair of slidably related members enabling them to be lengthened and shortened and co-acting springs on the said links, the inner ends of said links being pivotally connected to the inner hub member, the said links being disposed in groups, each group comprising a radial member and a pair of tangentially disposed members on opposite sides of the radial member, the inner ends of the members of each group having a common pivot connecting them to the inner hub member.

1,011,214. Wheel Fender. Frederick Lillich, Philadelphia, Pa. Filed July 26, 1911. Serial No. 640,566.

1. In a fender for vehicle wheels, the combination with an automobile, of hoods or casings pivotally mounted on the axle stubs of the front wheels of said automobile, and adapted to be held normally in an elevated position in relation to the said wheels, substantially as described.

1,011,217. Friction Transmission Gear. John Clinton Mackey, Detroit, Mich., assignor to Arbron Friction Gear Company. Filed Feb. 4, 1908. Serial No. 414,274.

1. A transmission gear comprising a drive shaft, a sleeve arranged to receive the same, said sleeve being normally rotatable on said shaft, a clutch member on said shaft, a driving gear actuated by said clutch, driven gears in mesh with and actuated by said driving gear, friction plates carried by said driven gears, a friction wheel mounted on said sleeve which mechanism communicates the movement of said shaft to said sleeve, a clutch member on said sleeve and a clutch member on said shaft, said clutch members being arranged for engagement to lock said sleeve and said shaft in such manner that said shaft may be revoluble uniformly with said shaft, substantially as described.

1,011,244. Carburetter. Thomas E. Puddington, Rochester, N. Y., assignor of one-half to Charles L. Briggs, Rochester, N. Y. Filed Aug. 31, 1911. Serial No. 647,076.

1. A carburetter, having a casing adapted to contain liquid hydrocarbon, the lower portion of which is a reservoir, an air inlet pipe leading thereinto, a carbureted air outlet pipe leading therefrom, a series of longitudinally disposed parallel branch pipes mounted in the casing and in communication with the air inlet pipe, each of said branch pipes having a plurality of nozzles, and a series of aprons one to each branch pipe, surrounding its respective branch pipe and having the lower ends thereof disposed with relation to the liquid within the reservoir to saturate the aprons by capillary attraction.

1,011,257. Apparatus for Priming Automobile Engines. Charles H. Smith, Rockford, Ill. Filed Dec. 2, 1910. Serial No. 595,185.

1. In an apparatus for priming explosive engines, a fuel supply tank, pipes conducting fuel therefrom to each of the engine cylinders, a valve controlling the flow of fuel from said tank, said valve comprising a hollow rotary valve member adapted to first receive a definite quantity of fuel and then discharge such quantity at each operation, valves controlling the entrance of the fuel into the engine cylinders, and means for operating all of said valves.

Sanford

Unfortunately there is but one competitor to Sanford Trucks

Chassis $1600

Stake or Express Body $1750

We're sorry about this in a way, for it narrows down our possible comparisons. But it makes it pretty easy for our representatives. There never has been a selling proposition in the field that can compare with the Sanford.

Nine long years' work on a one-ton truck gives you today this proposition, the success of which there is no gainsaying. There isn't a thing about this truck that's strange or freakish. Its success is not remarkable because of anything unusual.

The Sanford truck is remarkable only because it is so certain to do more than you'll claim for it that your repeat orders will be more or less automatic.

The Sanford Motor Truck Co.
SYRACUSE, NEW YORK

1,011,275. Internal Combustion Engine. Frederick A. Thurston, Lynn, Mass. Filed Feb. 26, 1910. Serial No. 546,116.

1. A two-cycle internal combustion engine comprising a cylinder, a closed crank case, a piston reciprocating in the cylinder, an inlet port in one side of the cylinder, an exhaust port at the opposite side of the cylinder, a transfer passage contained in the wall of the cylinder opening at its lower end in the crank case, being carried around the inlet port and opening at its upper end into the cylinder, and a conductor for explosive mixture having a connection with a carbureter, being secured to one wall of the cylinder and having one outlet at the lower end of the transfer passage and another outlet at the inlet port.

1,011,277. Anti-Skidding Device. Joseph Toren, Thornton, Ill. Filed Apr. 21, 1911. Serial No. 622,575.

1. The combination with a wheeled vehicle, of ground engaging means carried by a wheel of said vehicle and arranged to be moved into engagement with the ground; a shaft pivotally mounted on said vehicle; arms carried by said shaft; a bar carried by said arms; guides on the axle of said vehicle for said bar; springs arranged to hold said bar in inoperative position; cam shoes at the ends of said bar and arranged to be thrown into the path of said ground engaging means for rotating said shaft, substantially as described.

1,011,278. Headlight Controlling Device. Joseph Torma and John F. Orth, East Pittsburgh, Pa. Filed June 8, 1911. Serial No. 632,043.

1. In a headlight controlling device, a lamp support mounted for turning movement, a rock-shaft, connection between the rock-shaft and lamp support arranged for attachment to an element of the steering gear of a vehicle, an arm mounted for free swinging movement upon the rock-shaft, a link connecting the arm and clip, and a latch carried by the arm and engagable with the shaft to hold the shaft for movement with the arm.

1,011,311. Shock Absorber for Vehicles. Harry S. Bergen, Toledo, Ohio. Filed Sept. 2, 1910. Serial No. 580,210.

1. A spring suspension for resiliently mounting the body of a vehicle upon an axle comprising the combination with an axle of a pair of oppositely extending bell crank levers, one of the arms of each lever connected to the axle, a spring connected to intermediate portions of each lever and to the axle, and a pair of independently horizontally movable members for sustaining the body as to the axle and to which members the arms of the levers remote from the axle are connected.

1,011,332. Vehicle Wheel. Burt E. Dohner and Albert J. Huff, Dayton, Ohio. Filed Oct. 24, 1910. Serial No. 588,626.

1. In a vehicle wheel, the combination with a hub, and a two-part tire casing, of inner and outer retaining rings inclosed between the inner and outer circumferential portions of said casing, an inflatable tire inclosed by said casing and retaining rings, inner and outer clencher rims each consisting of two clamping members with extended circumferential portions which embrace the opposite sides of the casing for a substantial distance, and whereby lateral strain is more equally distributed to the wheel structure as a whole, said clencher rims clamping the inner and outer circumferences of the casing to the retaining rings, and bolts uniting the members of said clencher rims, substantially as described.

1,011,337. Roller Bearing. John F. Foster, Kansas City, Kan. Filed May 5, 1910. Serial No. 559,501.

1. In a roller bearing, a cone, a collar surrounding the same and tapered internally in the same direction as the cone and internally bearing a converging relation to the latter, a plurality of equi-spaced inwardly tapering rollers interposed between the cone and collar and holding the same spaced apart and reduced to form circular grooves between their ends, means projecting into the grooves of said rollers to limit excessive endwise movement thereof, and a cage rotatable with the rollers and consisting of a pair of rings and a plurality of equi-spaced spacers interposed between the cone and collar and adjacent rollers and secured at their ends to said rings; said spacers being diametrically reduced between their ends and in the vertical plane of the reduced portions of said rollers.

1,011,353. Automobile Tire Pump. Otto W. Linstrum, Hoopestown, Ill. Filed Mar. 12, 1910. Serial No. 548,999.

1. The combination with an automobile of a pair of superimposed oppositely disposed pump cylinders formed in one casting having an integral centrally arranged guide projecting from one end thereof; a piston in said cylinders; a scotch yoke mounted to reciprocate in said guide; operative connections between said yoke and said pistons; and an operative connection between said yoke and the engine shaft of said automobile, substantially as described.

1,011,449. Friction Transmission Mechanism. John W. Lambert, Anderson, Ind., assignor to The Buckeye Manufacturing Company, Anderson, Ind., a Corporation of Indiana. Filed June 9, 1910. Serial No. 566,002.

1. The combination of an engine with an engine shaft extending in opposite directions therefrom, a casing secured to each side of the engine in which the outer ends of the engine shaft are mounted, and friction transmission means mounted within said casing and in connection with said shaft.

1,011,469. Vehicle Wheel. Gabriel Mazzeo and Pasquale Iarussi, Newark, N. J. Filed Feb. 11, 1911. Serial No. 607,912.

1. A resilient tire for vehicles, comprising a casing, a plurality of tread-rims supported in continuous alinement exteriorly of said casing, tubular stems connected with said tread-rims, said tubular stems being adapted to penetrate within said casing, ribs or guides secured on opposite sides of each tubular stem, inwardly projecting lugs upon the interior side-portions of said casing, the free ends of which engage said ribs or guides to prevent said tubular stems from turning and said tread-rims from being moved out of their continuous alinement, coil-springs arranged within said casing and seated in each tubular stem to provide each tread-rim with an independent vertical and resilient movement, and a continuous shoe supported or carried by said tread-rims.

Tear This Out

Too Good To Keep.

The news we have received is so good that we must tell it to the whole motoring world.

The opinion of authorities on the subject is that the Start-Lite lighter has done more to simplify gas lighting problems and promote the comfort and convenience of the car owner than all other apparatus of a similar nature combined.

This means that every motorist whose car is equipped with gas head lights and a pressure tank must have a Start-Lite lighter to be completely satisfied - that every motorist who is having trouble with his electric plant can do away with both the trouble and expense.

We shall shortly make an announcement that will bring you to your feet with a jerk.

Tear out this page, fill in the blanks and let us tell you about the Start-Lite lighter and give you a little inside information on what we have in store for you.

Weed Chains

The Great Anti-Skid DEVICE

Nine-tenths of all accidents to automobiles are caused by skidding or slipping.

Either you skid into the "other fellow" or the "other fellow" skids into you.

No matter how careful a driver you may be, you cannot prevent skidding or slipping on wet, muddy snow-covered roads or on icy, slippery greasy pavements unless you equip your car with Weed Chains.

Cannot Injure Tires

Because They Creep

An absolute necessity on both rear wheels and if you want to know what real steering steadiness means put them on the front wheels too.

For your own safety—for the safety of the public, fully equip your car with Weed Chains. Make it your business to get a set today.

The New Twitchell Positive Lock Stop Gauge

There are many types of Gauges on the market, but do you really know of any that are accurate?

We Know Your Answer

Now listen to what we have to say about the NEW TWITCHELL POSITIVE LOCK STOP ACCURATE GAUGE:

1—Correct pressure is insured in all your tires.
2—Its construction is simple.
3—No rubber washers to wear out or deteriorate as in all other Gauges.
4—Absolutely no friction or wear on internal or external parts.
5—In testing this Gauge it passes through four different hands, the last test being inspection.

GET MILEAGE! Correct pressure, and pressure in all your tires are essential to your mileage.

The use of the new Twitchell Air Gauge enables you to attain this. IT IS ACCURATE, SIMPLE AND INSTANTANEOUS, made to carry in the vest pocket and is only 3½ inches long.

No better tire insurance could be produced than a STOP LOCK FEATURE TWITCHELL AIR GAUGE. It can be just as easily read at night as day—the graduated bar remains at the pressure indicated until a slight pressure of the thumb on the extreme end of the ratchet side returns the register to zero.

Correct Pressure for Tires:		
2½"	Tires.....	50 lbs.
3"	Tires.....	60 lbs.
3½"	Tires.....	70 lbs.
4"	Tires.....	80 lbs.
4½"	Tires.....	90 lbs.
5"	Tires.....	90 lbs.

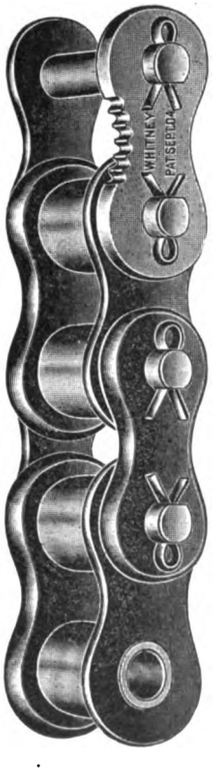
THE TWITCHELL AIR GAUGE IS TIRE INSURANCE FOR ONE DOLLAR.

Can be Obtained from Your Dealer.

THE TWITCHELL GAUGE CO., 1256 Michigan Blvd., Chicago. Ill.

WHITNEY

The Most Practical Chain for Motor Trucks



Because the "Whitney" Cotter Detachable Chain can be easily separated at any link and lengthened, shortened or repaired without the use of any special tool. This is of great advantage to truck builders, owners and drivers.

To have your truck equipped with "Whitney" Chains means greater mileage because they are made by specialists in a factory especially equipped for the making and are backed by years of experience. "Whitney" Chains are made from material chosen for quality regardless of cost, and all care taken in their manufacture makes them stand foremost. When making replacements insist on "Whitney" and get acquainted with its merits.

Mr. Automobilist:

Your tire maker is very anxious to impress upon you the importance of

Tires Inflated to the Right Pressure

He insists that this is tire economy and

Saves You Money

How do you know what pressure you have in your tires? A

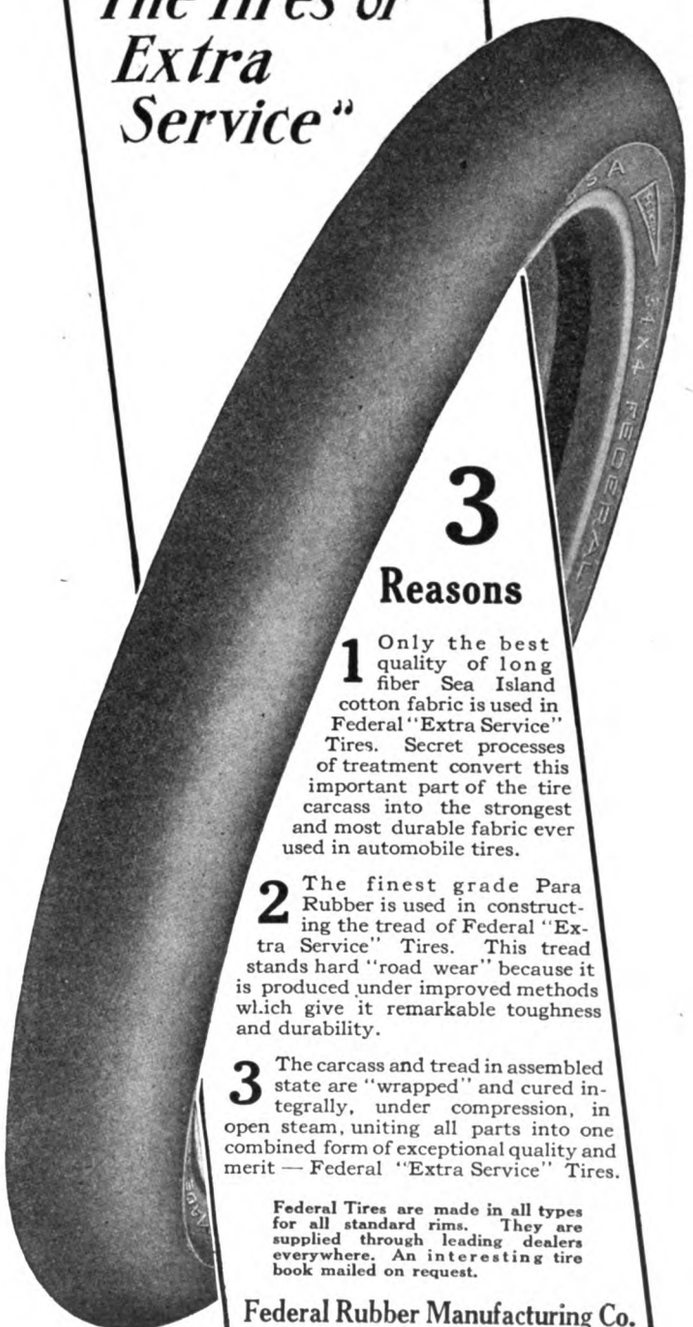
SCHRADER
UNIVERSAL
Tire Pressure Gauge

(Trade Mark Registered in U. S. Patent Office)

(Patented March, 1898—Other Patents Pending)

will tell the exact pressure in your tires at any time, day or night, by simply holding this Gauge to your Valve for a second. Its recording sleeve remains in place, showing the exact pressure in the tire so that the Gauge can be taken anywhere and read, at night to the front of the car into the light of the lamps. After the pressure has been ascertained the Indicating Sleeve can be pushed back into the Gauge with your finger. No catches or snaps to operate or get out of order. This Gauge is 2½ inches long over all, short enough to apply easily to the smallest diameter of wheel and can easily be carried in the vest pocket or the change pocket of your trousers.

Price $1.00 Each
Ready for Delivery Now



Guaranteed Simple and Absolutely Accurate

Can be obtained from all tire manufacturers and the dealers, or

FEDERAL TIRES

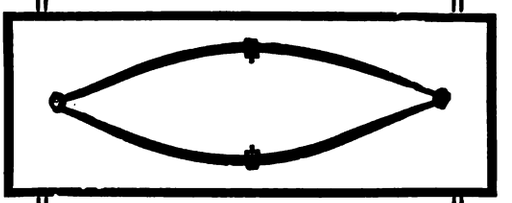
"The Tires of Extra Service"

3 Reasons

1 Only the best quality of long fiber Sea Island cotton fabric is used in Federal "Extra Service" Tires. Secret processes of treatment convert this important part of the tire carcass into the strongest and most durable fabric ever used in automobile tires.

2 The finest grade Para Rubber is used in constructing the tread of Federal "Extra Service" Tires. This tread stands hard "road wear" because it is produced under improved methods which give it remarkable toughness and durability.

3 The carcass and tread in assembled state are "wrapped" and cured integrally, under compression, in open steam, uniting all parts into one combined form of exceptional quality and merit — Federal "Extra Service" Tires.



Federal Tires are made in all types for all standard rims. They are supplied through leading dealers everywhere. An interesting tire book mailed on request.

OUR experience in spring making takes into consideration every material, heat treating and construction detail that tends to insure even tensile strength, and guard against friction and "fatigue."

WE are specialists in spring making with ample engineering and manufacturing facilities—all placed at the disposal of car manufacturers who want quality springs at modestly consistent prices.

PENN SPRING WORKS

Baldwinsville
New York

THINK THIS OVER very carefully and read it twice, if necessary.

Is there any part of an automobile engine, or any other gas engine, that is more important to its efficiency than a Valve?

Your engine leaves the factory running smoothly and sweetly—tuned up to its highest power. Perhaps the valves pit—warp—go out of shape—fail to hold compression. Then the power diminishes, and what can be more aggravating to the driver, who has known the fullness of the pulling power of his motor, than to have it grow less and less?

You cannot slight this part by putting in an inferior product—valves that will give trouble, or even break from inexperience in their manufacture—valves of unsuitable material, not suitably heat treated.

Too much is at stake, and a slight extra cost at the outset, which is the exception, may save you many times over a probable later expense.

This Company, with the experience of many years as a guarantee, will furnish you with properly made valves, of the materials best adapted to your requirements.

Not only QUALITY, but efficient SERVICE is a factor—surely there is a satisfaction in getting the kind of work you want—when you want it.

SCH

Schafer Ball Bearings

are built to withstand the most extreme strains and stresses of hardest service.. The durable, wear-resisting chrome steel used in their construction is of exclusive analysis, free from blisters, air bubbles and every intrinsic weakness that might cause the balls to vary in weight, size or structural strength. The balls are uniform to within .0001 part of an inch and remain so over long terms of hard service. Recognized by engineers as the highest grade and finest quality of anti-friction bearings made today. When you equip with Schafer you insure your car against frictional deterioration.

The Car THAT HOLDS THE CONFIDENCE OF ALL

Glide

36-42 H. P.
Complete Equipment
$1550.00

From the standpoint of actual service, utility and equipment, the "Glide" has won the confidence of all. First, the dealer handling the "Glide" has a car that he can sell with the assurance that it will satisfy the purchaser; second, the buyer actually gets more real automobile worth and efficiency out of the "Glide" than he can obtain from cars costing nearly twice the price. Send for handsome book and learn why the "Glide" is best. 5 to 7 years actual service is one reason—but there are many others.

Dealers—select territory still open. Write us.

The Motor With the Sliding Crescent Valve

KNIGHT-DAVIDSON
1896 — 1912

The CRESCENT valve of the K-D Motor, fitting around the stationary piston wall affords a larger port area than any other poppet or slide valve on the market. It is simpler and, consequently, better than any other valve construction known and is here offered to discriminating manufacturers, not as an experiment, but as a tried, tested and proved mechanical advance. The K-D motor is simple, silent, cools rapidly, has the simplest oiling system known, will not carbonize. Last and most important, will give on a given quantity of fuel more power, speed and endurance, unit for unit, than any other engine on any type of an automobile. We want to present some facts to interested manufacturers.

KNIGHT-DAVIDSON COMPANY, Boston, Mass.

They Barred the Franklin Out

The Quaker City Motor Club of Philadelphia conducted an economy run for motor cars April 27, open to all pleasure cars with the exception of air-cooled cars.

What They Did

In the Quaker City contest, open only to water-cooled cars, first prize for economy was awarded to a two-passenger car that averaged 22.7 miles per gallon of gasoline.

What the Franklin Has Done

46.1 miles on one gallon of gasoline in the economy contest conducted by the Automobile Club of Buffalo.

87 miles on two gallons of gasoline in the economy run held by the Automobile Club of America.

Studebaker

The $800 Studebaker-Flanders "20"

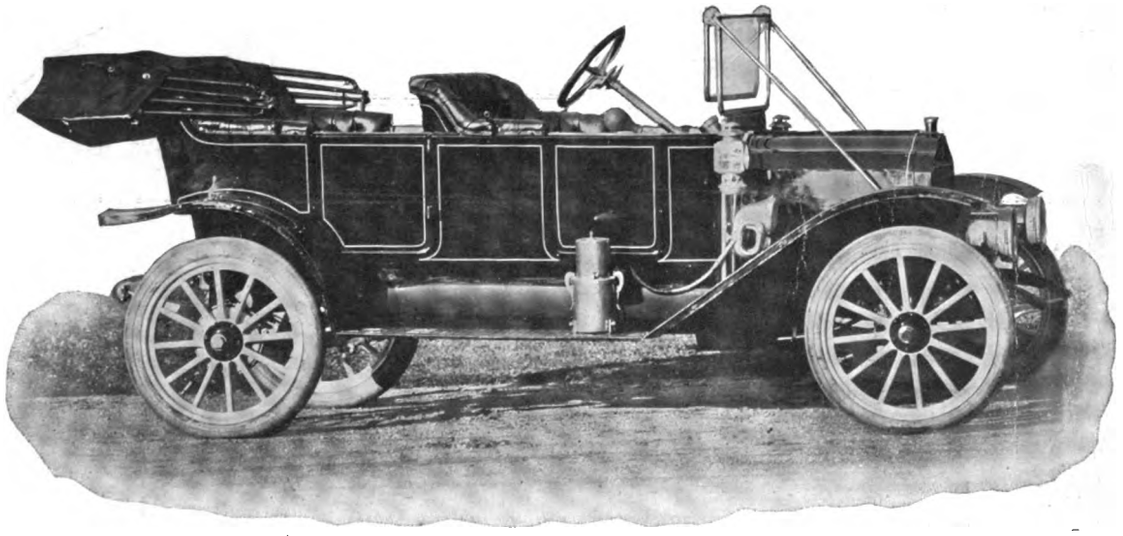
The Studebaker-Flanders "20" has a tremendous price advantage.

No other car, offering as much value approaches its price.

Think for a moment what you get when you buy a Studebaker "20."

It is a real car, modern throughout in design and construction, large enough, and so powerful that you will never find road conditions in which your Studebaker "20" cannot spin its wheels.

The motor is a marvel, very speedy, quick to pick up, flexible, the kind of a motor a driver grows to like and have full confidence in.



The Studebaker "20" transmission system is of the standard three speed type, any car speed you wish up to 55 miles an hour. The rear axle is remarkably well designed and built, giving the best of service.

Every Studebaker "20" body gets 17 coats of paint and varnish, which are properly rubbed and aged. If you take care of your car, your Studebaker body will equal any automobile body on the market.

These are some obvious points which show the car's value.

But the deeper you go into the design and manufacture of the Studebaker "20" the better you will like it. We watch every detail.

Every Studebaker "20" is built not only for the first mile but for the 20,000th mile. In those qualities which make for endurance and lasting satisfaction, the Studebaker "20" is incomparably first. Why? Because it is Studebaker-built, and Studebaker always builds that way.

Studebaker-Flanders "20" Touring Car, $800, f. o. b. Detroit.
Equipped, as above, with Top, Windshield, Prest-O-Lite Tank and Speedometer, $885.

Sell Delivery Cars That Merchants Want. Live Dealers Find Ready Market For Lippard-Stewart Cars.

LIPPARD-STEWART commercial vehicles are classed by experts as "the best dollar-for-dollar delivery cars on the market. They are built after careful investigation of the needs of merchants in all lines of business, big and little, and with particular attention to the points which were brought out by actual talk with tradesmen and manufacturers, as being desirable or undesirable in a commercial car.

We believe that a car built as this has been, by careful engineers considering the users' problems as well as the manufacturers', is sure to meet the complete approval of all its users. These cars have been subjected to the most strenuous tests in actual service and have proved themselves to be ideal for all purposes.

The many features which commend Lippard-Stewart delivery cars to the careful consideration of all prospective buyers of delivery cars are:

Four-cylinder Monobloc Motor, long stroke, slow speed, 22 h.p., five to one gear ratio in rear axle.

Selective Transmission. Vanadium steel heat-treated gears. 1-inch face.

Multiple Disc Clutch. Steel and Raybestos discs. Clutch case integral with transmission.

Special Timken Rear Axle. Full-floating type; 17-inch brake, 34-inch wheels.

Bosch magneto, single ignition. No batteries, timer, coil, etc.

Thermo Syphon Cooling. No water pump and connections.

Special Spring Suspension. Full elliptic in front, long semi-elliptic and auxiliary coil springs in rear.

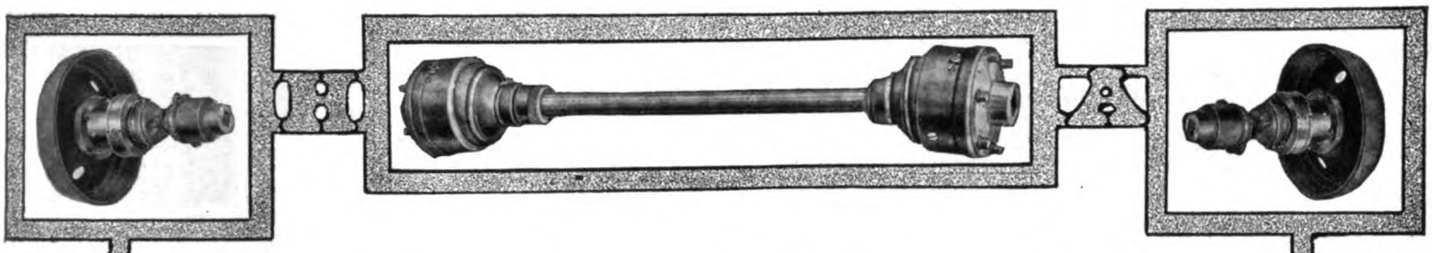
Every Part Accessible. Each unit can be removed, if necessary, without disturbing any other unit or the load.

Left-Hand Steering. Levers in center at driver's right hand.

Handsome Lines, Beautiful Finish. A Lippard-Stewart car is a constant advertisement for the owner. It shows that he is progressive and up-to-date.

Lippard-Stewart delivery cars have no seasons or weather conditions. They are at the owner's service twenty-four hours a day, if necessary, and can be depended on for rush work at any time. They out-work the best possible horse delivery at much lower cast and save money at every point.

An Opportunity for You



We have openings for a few more dealers. Perhaps yours is a town in which we are not yet represented. At any rate, it will do you no harm to find out. Write for our proposition to dealers and let us show you the money-making possibilities of handling the Lippard-Stewart line.

You will get some valuable information by just seeing the Lippard-Stewart commercial vehicles. Let us show you these cars at our salesrooms and help you get what you need.

A concern such as this must exist and enlarge on its ability to produce clutches and universal joints that will stand the expert scrutiny of automobile engineering experts.

That we are building such parts is self evident—because new business is coming to us and old business is sticking.

Hartford clutches and drives are standard on many of America's leading cars. 1913 will see still further enlargement.

F-400 BEARINGS RINGS
Made from 25 Carbon Steel Forgings

We show here a picture of one of the scores of stacks made up of finished universal parts—and our factory floors are loaded to their limit with these disassembled parts awaiting collection and shipment.

Surely this is a sign of healthy business—one built only on the advertising that comes with good reputation.

We want to put Hartford quality parts on still more quality cars—and the first order from a new customer will prove—

Right products at the right price at the right time.

Between seasons is the time to get in touch with the parts people—and that time is now.

EXPERIENCE – SHELDON – RIGHT DESIGN
FACILITIES – AXLES – RIGHT STEEL

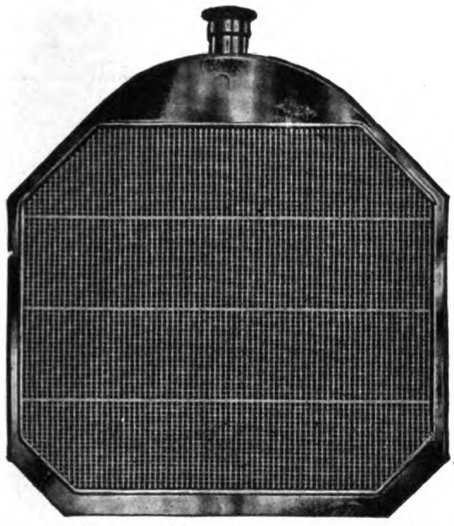
"Made in the Largest Axle Factory in the World"

Axle Talk—No. XI

The car that bears as one of the specifications, SHELDON axles, is a car that can be safely relied on to embody quality in its other parts.

We believe that the average car manufacturer is willing to pay for quality—at least we have found it so in our particular business, for SHELDON axles are not by any means the cheapest—and yet when the price is considered along with the service rendered, they are in the end the most economical for the ultimate user.

We again call attention to the pronounced special features characterizing the SHELDON front axle as illustrated here, with particular reference to the fact that these axles are drop forged from end to end—that even the spring seats are parts of the original bar of steel.



Design, material and manufacture all unite in forming SHELDON standard—a standard that is known wherever cars are known.

Our Engineering Department stands ready to co-operate with you, Mr. Car Manufacturer, in the matter of putting the right kind of axles on the right kind of pleasure cars and commercial trucks.

Designed especially for use on Torpedo body or Fore-door cars. Set consists of two strong arms firmly bolted to running board and permitting of sufficient adjustment to accommodate two tires or demountable rims, of standard sizes, 4 inch or smaller. Made of solid Brass and guaranteed to give perfect satisfaction.

Finish: Furnished in Hard Rubber Black Enamel finish, and full Polished Brass.

	Brass	Black
Price, complete with Straps...	$4.00	$3.00

A dozen other styles and sizes in stock. See catalog.

Our 1912 Catalog, which is held as a book of reference by manufacturers, dealers and automobile owners, will be mailed on request. Circulation limited to 100,000 copies.

Costs little to Buy

Costs Nothing to Operate

It Never Fails

$18.

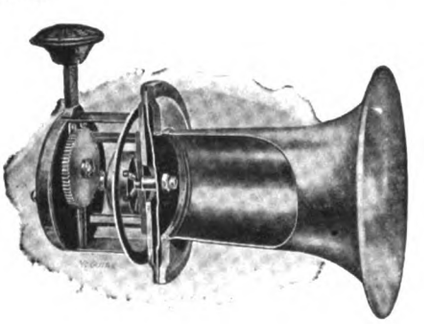
THE LONG HORN

$18.

You Can Make the Warning as Loud or as Soft as You Wish

There is no signal on the market, electric, exhaust, or otherwise, which is the equal of the Long Horn for use on an automobile.

In the first place the Long Horn will never fail—just so surely as you press the button you issue a warning—loud and long, if you wish it—or soft and short, if you wish it. The volume of tone depends upon how hard you press the button.



The Long Horn Is Not an Electric Horn

It is the superior of any electric horn made even when that electric horn is working, and yet it costs only about one-third as much as the best electric horn.

The Long Horn eliminates all chance of failure found in all other horns, such as the breaking down of the motors, running down of the batteries, cracking of bulbs, etc.

Certainly, the Long Horn offers a mighty attractive proposition to dealers everywhere if those dealers are live enough to push the leader of all warning devices.

If Long Horns are not already represented in your territory, why don't you write us at once. It will be to your interest.

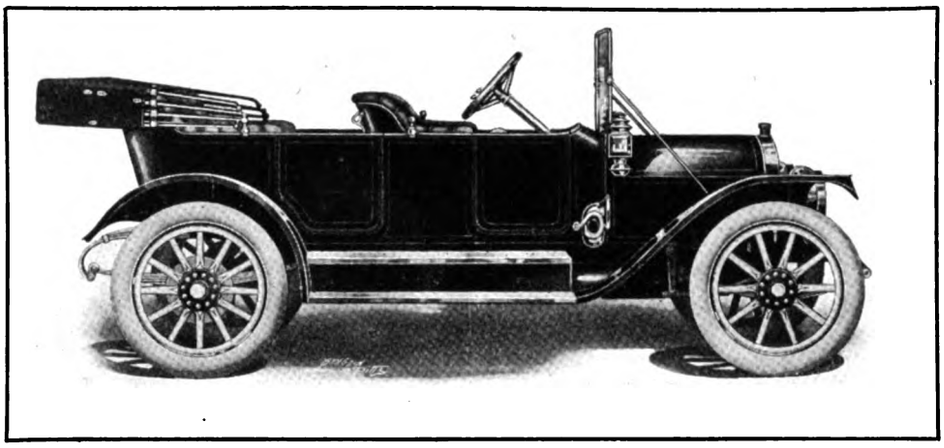
"45"—$1400



PENN CARS

"30"—$1000

The average dealer wants a line that appeals to PURCHASERS. The PENN line does that. Value dominates each model.

BY EVERY TEST of performance, the PENN car is the only one that satisfies the greatest number of requirements—it does everything that can be done with any car—goes where ANY CAR CAN GO, and at a lower cost. PENN cars have a distinctive style of their own—the two chasses being equipped with beautifully modeled bodies of various types, all of them perfect bits of body-builders' art—wherein the perfection of line and the beauty of workmanship are everywhere apparent. The bodies are as perfect in their classes as the chasses are in theirs—the kinds that, while pleasing the eye with their graceful lines, one remembers longest for their comfort and convenience.

Model "T-4"

30-H.P. $1100

The most we can hope from this advertisement is to get you to look at the PENN cars and to have you compare them. But don't limit your comparison. Compare them with cars costing more.

THE PENN TWO PASSENGER FORE-DOOR ROADSTER	30-h. p.,	$1000
THE PENN TOURING CAR	30-h. p.,	1100
THE PENN "PIRATE" ROADSTER	45-h. p.,	1350
THE PENN TOURING CAR, FIVE-PASSENGER	45-h. p.,	1400

The PENN 45 touring car is the most and the best that $1400 ever bought. It's a large, roomy, luxurious five-passenger car, wheel base 115 inches and 34-inch wheels, 45 horse power motor, annular ball bearing transmission. This car belongs to the $3000 class, body, design, equipment, upholstery—all the very best that money can produce.

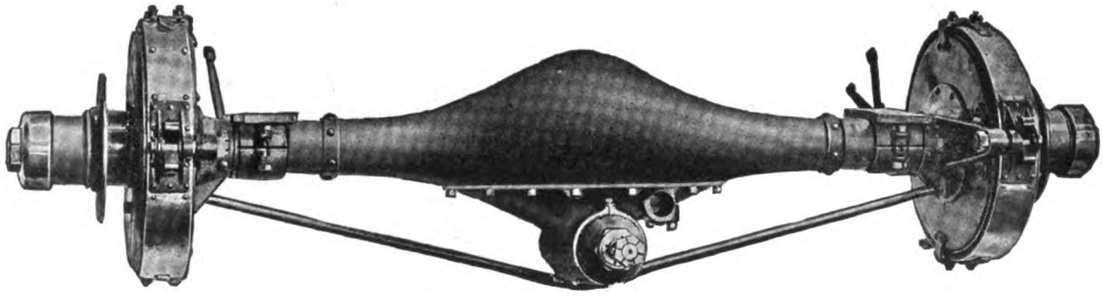
American Axles

Poor Axles Will Rob Your Electric's Batteries



Do you know that the amount of service your battery gives is based squarely upon the quality of your axles?

Do you know that the more current used to overcome mechanical difficulties, the less remains for motive power?

Do you know that *American Axles*, with their patented features ensuring easy running, are of tremendous importance in securing maximum mileage?

We designed and manufactured the first successful Bevel Drive axle suitable for use in electric vehicles, giving it the refinement demanded for this exacting service.

We also build the famous Lanchester-Daimler Worm Gear axle, holding the exclusive American rights as axle manufacturers through the Warner Gear Company, of Muncie, Ind.

The True Meaning of the Word "Service"

Model "H"

The Regal "35" Underslung Touring Car, $1400

A MUCH ABUSED WORD—is this word "Service." In a hundred pieces of publicity you will see it used indiscriminately, unrelated to its true meaning as it affects the dealer and the purchaser of Motor Cars. Used as a stop-gap for lack of something to say—merely to fill out space, as if the writers of automobile "copy" were brain fagged and needed a prop, a support for the re-arrangement of their wearisome, reiterated adjectives.

THE WORD "SERVICE" has several meanings in its relation to the building and marketing of automobiles, all of which are co-related and apply on one perfect service that by right is demanded by dealer and purchaser today, but any one of these meanings, applied separately, reduces the true meaning of the word to a commonplace, of very little advantage, if any, to dealers or the public they serve.

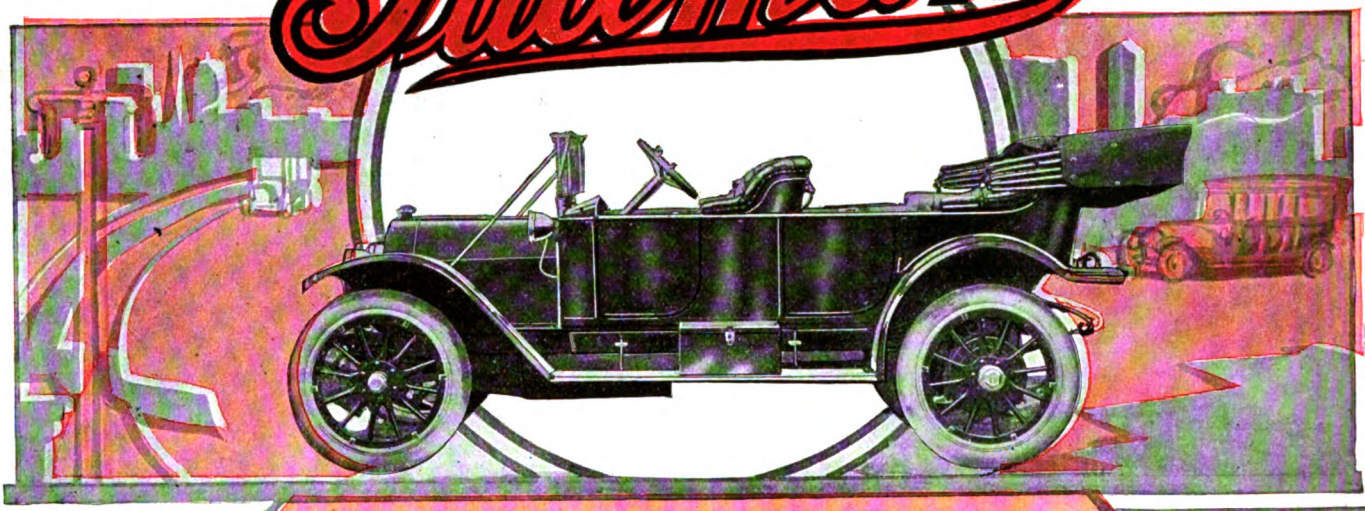
WHAT IT DOESN'T MEAN. Service doesn't mean that a dealer who sells a car is responsible for its quality, for its design, for its monetary fair value. Service doesn't mean that because a dealer sells a certain car he therefore guarantees it against defective material, or the breaking of parts through excessive stress or abuse. Service doesn't mean that should accident happen the owner has to wait days, or weeks, for parts necessary to effective repair. Service doesn't mean that when a car is purchased the transaction between seller and buyer is ended. Service doesn't mean that because a manufacturer happens to have a few hundred dealers, or less, scattered over the country, the owners of that particular make of car are protected against inefficiency.

SERVICE TRULY MEANS the opposite of all these opinions or beliefs. It means a manufacturer behind the dealer, who guarantees his cars, qualities, designs and just values. It means protecting the purchaser direct against defective material and the immediate supply of parts broken by accident or abuse. It means a factory, that through its each and every dealer is vitally interested, always, in the efficient performance of every car in the hands of owners. It means, also, a perfect organization to guarantee the true expression of the word "Service."

THIS IS REGAL SERVICE. A co-partnership that makes for the dealer the selling of Regal cars a pleasure instead of drudgery. A business-building service, for it creates satisfied customers. REGAL SERVICE WAREHOUSES are placed at strategic points all over the country. They carry complete stocks of cars and parts for immediate delivery. They are really dealers' warehouses and guarantees to owners of Regal cars for the highest efficiency of every Regal car in service. These warehouses prevent delay and vexing annoyance. They give a greater value to every Regal car sold than can possibly be included in the purchase price.

THE REGAL "35" UNDERSLUNG TOURING CAR is not only a car inbuilt with the most advanced engineering practice in design, but is also one of the distinctive Regal family of "Underslungs" behind which is the Regal Perfect Service. A car that completes the Regal Comprehensive Line, giving every Regal dealer an opportunity of sale, for there is a Regal car for every purchaser's preference, ranging in price from $900 to this beautiful, roomy, powerful Underslung at $1400. Because the Regal line is a year ahead in construction, because Regal cars are more than moderate in price, excelling in quality and values, and because Regal Service is behind and offered free with every Regal car—it pays to be a Regal dealer —because it pays in economy and efficiency to be a Regal owner.

SOME SPECIFICATIOINS. Motor, 35 H. P., 4 cylinders (in pairs) 4¼ x 4½; wheel base 118 inches; Morgan & Wright tires, 34 x 4; demountable rims (one extra furnished free of charge); three speeds and reverse, selective sliding transmission. Hyatt nickel steel roller bearings. Dual ignition with magneto—standard equipment—two gas searchlights, two side oil lamps—tail lamp, generator, tools, jack, pump, etc.



OTHER REGAL CARS WITH REGAL SERVICE. The most advanced construction, lowest price, highest quality car for 1912—the New Regal "25" Underslung Touring Car, $950. The famous (biggest seller) Regal "25" Underslung Roadster, $900. The Regal "25" Underslung Colonial Coupe, $1250.

1913 Pullman 1913

Pullman

Built for Service

Pullman

FOR 1913 the Pullman Motor Car Company offers the Pullman 4-36; Pullman 4-44; Pullman 6-66. These three models compare very closely with the three leading models for 1912. The changes in design are largely confined to refinement of details, increase of power and fuel capacity.

The radiators have all been enlarged in capacity, the oil reservoir on the larger models has been considerably increased in size, as have also the fly wheel and clutch. The steering wheel has been made larger in diameter on all models and both the front and rear springs have been considerably lengthened.

In addition to this there has been a general addition to the equipment to such an extent that there is nothing left for the owner to buy to make the equipment of his car absolutely complete.

The 4-36 motor is 4 1-16 inch bore by 5 inch stroke, with cylinders cast in pairs and exceptional large valves 2⅛ inches in diameter. All of the parts and accessories are standard and accepted leaders. This model comes in six different body styles, from a roadster through the various modifications to the limousine. The retail price of the regular five passenger 4-36 is $1675.

The 4-44 motor is 4½ inch bore by 5½ inch stroke, with cylinders cast in pairs, large valves, with its rated horsepower developed at only 1300 r. p. m. This model carries four speeds forward and one reverse. The wheel base is 122 inches. The body comes in seven different styles with the regular stock body and equipment priced at $2150. This model, in addition to being equipped with a self-cranking motor, carries a complete electric lighting outfit.

The Pullman 6-66 motor consists of six vertical cylinders, 4½ inch bore by 5½ inch stroke, cylinders cast in pairs, with its rated horsepower developed at only 1300 r. p. m. This model carries four speeds forward and one reverse and has a wheel base of 138 inches. In addition to the motor being self-cranking, this model is also equipped with a complete electric lighting outfit. Price of this model with regular body is $2750.

"THE PALACE CAR OF THE ROAD"

PULLMAN MOTOR CAR CO., York, Pa.

1913 Pullman 1913

Pullman

They Lead the Leaders

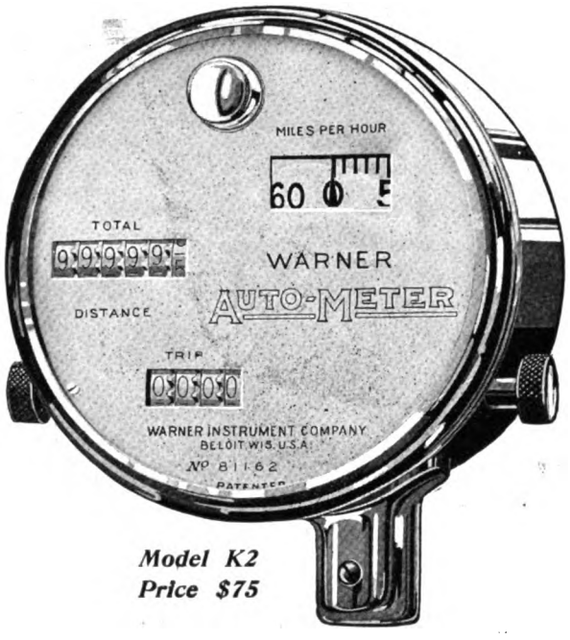
Pullman

THESE specifications cited here of course are very meager, serving only to indicate the general outlines of each of the leading models for 1913. Full detail specifications will gladly be furnished upon application.

We wish to impress thoroughly upon the trade that all Pullman cars are manufactured by the Pullman Company and not assembled. As stated above, the accessories, such as carburetors, magneto, batteries, bearings, etc., are all manufactured by the accepted leaders in the industry.

No car manufactured at any price is more carefully built than the Pullman. The factory work is as fine and exhaustive as it is possible for skilled mechanics to produce.

What the Pullman Motor Car Company wishes most thoroughly to impress upon dealers throughout the country is the fact that it is looking only for representation of the highest order. The Pullman product is an asset to the dealer only because of its intrinsic merits—not because of excessive commissions and unbusinesslike concessions.



Pullman dealers are bound to succeed not because they make an exorbitant first profit, but because their customers having once used a Pullman car continue to use Pullman with little or no effort on the part of the dealer. Cost of up-keep and service to the customer is an absolute minimum with Pullman dealers.

There is still some good territory open and if you can qualify to our standard we have a very attractive proposition for you. Send us your name and address at once and we will furnish you with complete details as to the Pullman 1913 specifications, also complete information regarding our agency proposition in your territory.

Model K2
Price $75

Warner AUTO-METER

FOR 1913 the world's largest automobile manufacturers will equip their cars with Warner Auto-Meters. Over 100,000 new cars will carry Warners as regular equipment.

Having decided to carry a speed indicator as "regular equipment," it naturally followed that the highest grade cars would select the highest grade speed indicator made. The Warner was selected. When it came to a final and thorough test the Warner proved its superiority under every possible condition.

Examine the speed indicator on the car you buy, for a manufacturer's equipment is a good guide to the whole character of his product.

Priced from $50 to $145. For sale at our own branches and by leading dealers all over the world.

Handsome catalogue on request.

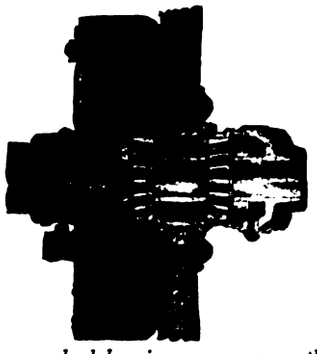
A Timken Roller Bearing, showing its cone, rollers and pressed-steel cage, but not the cup which fits over them.



Front-wheel bearings must meet side-pressure often in excess of the vertical load.

Good bearings in the transmission keep shafts in line and gears in mesh—saving power.

Good pinion and differential bearings also mean efficient transmission of power—saving gasoline.

The rear-wheel bearings carry more than half the car's weight and burden.

Good bearings play a big part in getting every last mile from each gallon of gasoline, and in holding down the repair expense.

In the transmission, at the pinion shaft and the differential, bearings worn loose mean shafts out of line and gears out of mesh. These make noise and consume extra power which is extra (wasted) gasoline.

The utmost of power from the engine and the lowest of upkeep expense can only be had when the bearings fit snug and run smooth—all the time—for the life of the car.

TIMKEN
TAPERED ROLLER BEARINGS

Have Greatest Resistance to Wear

The Timken Bearing is made of special, Timken-analysis steel.

The steel is carbonized and heat-treated to make its surface glass-hard but not brittle.

Underneath the surface the steel is left tough and elastic to cushion the shocks.

The Load is Distributed

Load, on the Timken Bearing, is distributed over the entire length of its rollers, not concentrated at points, as is the case in a ball-bearing.

This wide distribution of load keeps pressure, and hence wear, down to the minimum.

The Timken principle of tapered rollers revolving about a tapered cone with two ribs—makes a bearing that takes end-thrust at the same time it is carrying vertical load.

And the end-thrust, too, is distributed along the length of the rollers.

So in material and its treatment—in principles of design—and in actual practice in thousands of pleasure and commercial cars—it is theory proved true, that—

Timken Tapered Roller Bearings offer the greatest possible resistance to the inevitable wear.

And when wear does come it can, in the Timken, be entirely taken up by adjustment without the least impairment of efficiency.

Are Adjustable (perfectly) for Wear

In every place where they are used, the bearings should keep shafts in alignment, keep gears in correct mesh, support the loads, take the "end-thrust," and all the time, hold friction down to a negligible quantity.

They must do these things when the car is new and they should do them when the wear inevitable comes.

There is no getting away from wear and there is no getting away from the necessity for adjustment to take up that wear

The Only Perfect Adjustment

Timken Bearings, like any good bearings, will show wear in time.

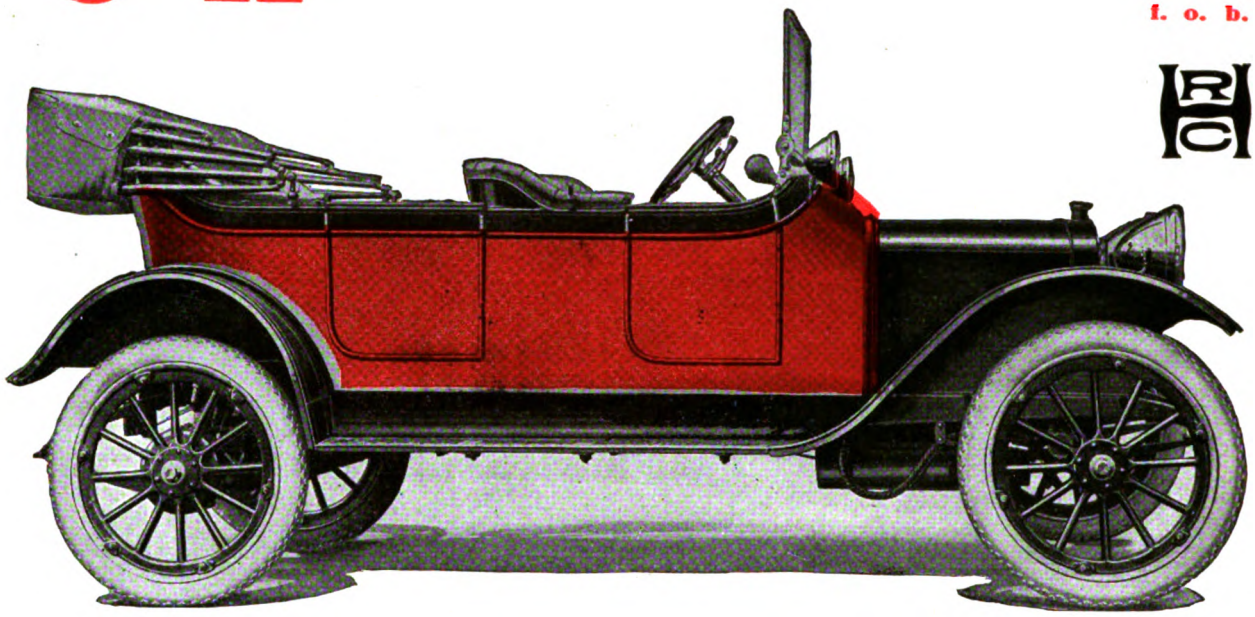
But the Timken has this advantage over all other types of anti-friction bearings—

It can be adjusted to completely take up that wear without the least sacrifice of efficiency.

The two ribs on the Timken Cone keep the tapered rollers always in perfect alignment—therefore the diminutive wear is uniform over the surfaces of cone, rollers and cup.

When the cone is moved just a trifle farther into the cup all parts are brought into the same identical relation as when the bearing was made.

No grooves can wear in the races. The rollers, though microscopically smaller, have still the same taper and, after adjustment, are just as snugly in perfect rolling contact with cup and cone as they were at the start.



THE TIMKEN ROLLER BEARING CO., CANTON, OHIO
THE TIMKEN-DETROIT AXLE CO., DETROIT, MICH

For more than 14 years the Timken Roller Bearing Axle (made at Canton, O.) has been giving satisfactory service in horse-drawn vehicles

R-C-H "Twenty-Five" $90

f. o. b. Det

The Car

WHEELBASE 110 inches.

MOTOR Long-stroke; 4 cylinders cast en bloc; 3¼ inch bore, 5-inch stroke. Two-bearing crank shaft. Timing gears and valves enclosed. Three-point suspension.

DRIVE Left Side. Irreversible worm gear, 16-inch steering wheel. Spark and throttle control on steering column.

CONTROL Center Lever operated through H-plate integral with universal joint housing just below. Hand-lever emergency brake at driver's right. Clutch pedal operated by left foot. Service brake operated by right foot. Foot accelerator in connection with hand throttle.

SPRINGS— Front, semi-elliptic; rear, full elliptic and mounted on swivel seats.

FRAME— Pressed steel channel.

AXLES— Front, I-beam, drop-forged; rear, semi-floating type.

TRANSMISSION— Three speeds forward and reverse; sliding gear, selective type.

CONSTRUCTION Drop-forgings wherever practicable; chrome nickel steel used throughout all shafts and gears in the transmission and rear axle; high carbon manganese steel in all parts requiring special stiffness.

BODY Full 5-passenger English type; extra wide seats; 10-inch seat cushions specially upholstered.

WHEELS— Artillery type.

The Equipment

Non-skid tires, 32 x 3½.
12-inch Bullet electric head light with double parabolic lens.
6-inch Bullet electric side lights with parabolic lens.
Bosch Magneto.
Warner Auto-Meter.
Demountable rims.
Extra rim and holders.
Tally-ho horn.
Jiffy curtains — up or down instantaneously.
Top and top cover.
Windshield.
Rear view mirror.
Tool-kit, Jack, Tire Repair Kit, Pump.
Robe Rail.

"OPPORTUNITY"

"Opportunity knocks once at every man's door" is an and threadbare saying. Whether or not **opportunity** ha the past knocked at your door, whether or not it will in future, is of no interest at this particular moment.

The most important point is that opportunity is knoc at your door **now.**

Here is the proof:

The R-C-H for 1913 is acknowledged everywhere to be greatest selling proposition ever offered to automobile dea

Consider these facts:

Many manufacturers are now idle for various reasons

Some of them are taking summer vacations.

Others have closed their plants for inventory and rep

Others are between seasons.

One or two have orders up to their capacity, and ca accept additional orders at this time.

The R-C-H plant, however, is working **night and day.**

We have been delivering, since the appearance of the models, **better than 50 cars a day.**

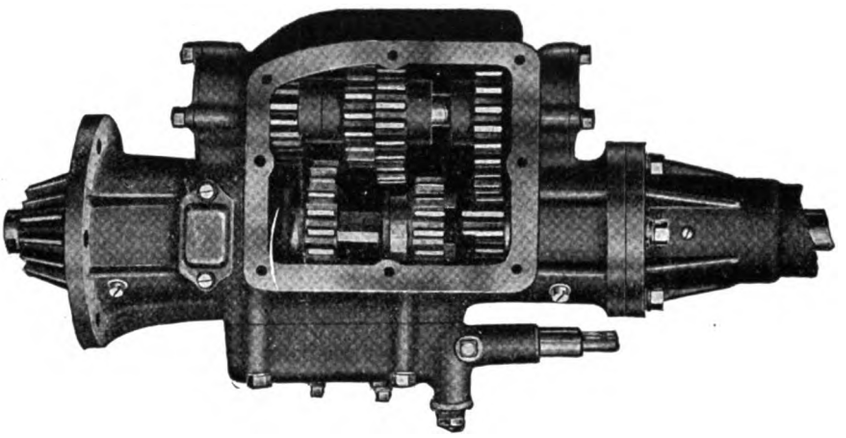
You can get the cars. Many of your competitors **ca**

The public is buying cars **now.**

This is your **opportunity.** Get the business while competitors are forced to be idle.

Then, too, remember that we are backing the whole pr sition with a National Advertising Campaign, the effici and extent of which have never been exceeded in this indu

The opportunity to "make a killing" with an R-C-H presents itself to you.



Now is the time. **Now** is the opportunity. It is ent within your power, Mr. Dealer, to accept or reject it.

R-C-H CORPORATION, 104 Lycaste Street, Detroit, Michig

Branches — ATLANTA, 548 Peachtree St.; BOSTON, 563 Boylston St.; BUFFALO, 1225 Main St.; CHICAGO, 2021 Michigan Ave.; CLEVELAN Euclid Ave.; DENVER, 1520 Broadway; DETROIT, Jefferson Ave. and Lycaste St.; KANSAS CITY, 3501 Main St.; LOS ANGELE South Flower St.; MINNEAPOLIS, 1206 Hennepin Ave.; NEW YORK, 1989 Broadway; PHILADELPHIA, 330 North Broad St.; FRANCISCO, 819-835 Ellis Ave.; WALKERVILLE, ONT., CANADA.

COVERT

Commercial cars equipped with COVERT TRANSMISSIONS of proper size are immune to transmission troubles.

COVERT TRANSMISSIONS are specialized—our whole time and thought is given to their perfection and manufacture, in which we have incorporated the result of fourteen years experience. We have "ironed out the kinks" and refined the strong points.

Our manufacturing equipment is the last word in specialized machinery. By long practise our men have becime highly skilled along this line—they turn out better, and more work than is possible for an organization not so trained.

Specialized motors, axles and wheels, are better and cost less. The same applies to COVERT TRANSMISSIONS—whether one of our standard Jack Shaft or Rear Axle models, or for Unit Power Plant, or Sub Frame suspension.

A Perfect Starter At Last!

Energetic Dealers Wanted

A rare business opportunity. Live dealers throughout the entire world wanted to represent us and to install the National Starter

The First Perfect Mechanical Starter

It has always been said that if a *perfect* starter could be built—a *dependable* starter—one that would start the engine from the seat and forever do away with dangerous cranking—that such a starter would revolutionize motoring—that it would add the final touch of perfection to the automobile.

—and now, after years of experimenting, comes the first *perfect* mechanical engine starter—the NATIONAL STARTER—the *only* starter that is actually 100% efficient.

Works *every* time.

No batteries—no tanks—no wiring—no piping—no springs. Nothing but simple ball-bearing gearing.

Dealers in automobiles and accessories, and garage owners will instantly recognize the tremendous business possibilities of this new starter.

The Principle of the National

The National is built on a patented principle.

It is purely mechanical.

A simple pressure of the foot and the engine turns over—just like cranking.

The powerful leverage which is obtained through gear reduction turns the engine over easily—*so easily that you can start on the magneto just as readily as on the batteries.*

The National works equally well in hot or cold weather. It is *not* dependent upon acetylene gas, compressed air, gasoline, electricity or springs. It develops its entire energy through the slight pressure of your foot on the dash pedal—like a clutch. In case of back-fire the National automatically disengages.

We have subjected the National to the severest tests. We have tried it out in all sorts of weather and on all sorts of cars. We made it *prove* its merits.

And now we back every National with an ironclad guarantee for one year.

Easy to Install—Easy to Operate

The National can be installed on any car in about two hours' time. It is fastened to the front of the car in place of the crank. Total weight is about 15 pounds.

THE NATIONAL GAS ENGINE STARTER COMPANY
Dept. 551B, 30-32 N. Dearborn St., CHICAGO, U. S. A.

Car Owners: *Write us for literature and name of nearest "National" dealer.*

Manufacturers: *Write us for literature and our offer to install the National as standard equipment.*

A ten year old child can operate the National easily. One pressure of the foot—the crank shaft turns—the engine starts. Just a simple mechanical operation.

A Big Business Proposition

The tremendous demand for a *perfect* starter makes the selling end of the National only a matter of proving its merits. *Thousands and Thousands* of car owners will install the National as soon as they see it.

They'll want the advantages of the National for themselves as well as to enable the women-folks to drive.

You see the field is practically boundless.

Big business men consider this a big enough proposition to *open up special demonstrating salesrooms for the exclusive sale of the National.*

They realize the wonderful possibilities of the National.

The retail price of the National is $50.00 *completely installed.* Figure out approximately the number of cars in your territory and you will have an idea as to how broad a proposition this is.

Applications for Agencies Now Being Received

Already we have received thousands of applications for National agencies. We are literally *swamped* with requests. South America, England, Germany, France—energetic dealers in all these countries have applied for National agencies as well as thousands of American business men. But we are prepared to meet the tremendous demand.

THE NATIONAL STARTER
TRADE MARK

We have practically unlimited manufacturing and financial resources.

Agencies for the National Starter are now being allotted. Applications will be handled in the order in which they are received.

Wire us, and come to Chicago if you can—let us show you just how the National is built—let us tell you in a personal interview the tremendous business possibilities of this proposition.

If you cannot come, write us. Full information and large descriptive circular can be had by signing and mailing the coupon.

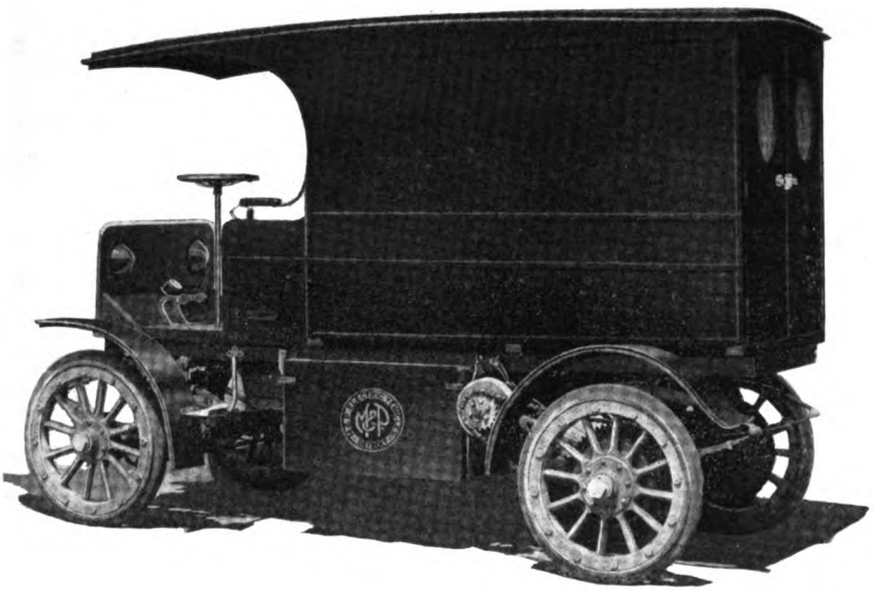
1000 lb. Electric Truck

Standard in Every Detail

WE stated in a previous advertisement that the M & P Electric Truck was built before the selling price was decided upon.

In our initial plan and all the way through the processes of designing, building and finishing, we had quality in mind—quality that would mean service to the user.



After this truck was completed to our satisfaction, we made the price — $1500 (other prices noted below).

You, Mr. Dealer, can offer to your trade the M & P Electric as embodying all of the good features and dependable worth of the electric truck that has, heretofore, sold from $2200 up.

You can put this machine within the reach of those who have heretofore been forced to be content with the cheap 1000-pound gasoline truck that sells for from $1000 to $1500.

You can offer (and we will prove) economy of operation and service double in value to that of a similar priced gasoline truck.

Remember the M & P Electric Truck is the finished product of long experiment, wherein the weak points common to other trucks have been eliminated, other features made stronger than ordinary and, as completed, a machine perfect in every detail.

There is money in this proposition for you — more, there is satisfaction that comes with selling dependable goods. Both are at your command and we solicit opportunity to go deeper into this subject with you.

THE PRICES: Chassis $1450 : Express Body $1500 : Enclosed Body $1600

"The Horn that's Made for the Discriminating"

TUTO HORN

THE TWO TONE HORN

Why the Bulb Horn Is Retained.

IT is not necessary to argue and try to force intelligent motorists to put up with inflexible methods of signalling.

¶ The bulb horn is acknowledged inadequate for emergency purposes.

¶ Furthermore, the loud warning signal is completely unfit for all of the signalling.

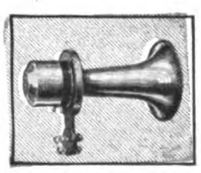
¶ You would not shout a request when it can be made in a mild tone. It would be insulting to say the least.

¶ Neither would you whisper a demand when life, limb and property is at stake. This would be fool-hardy.

¶ Your warning signal must be capable of requesting firmly, but not extremely loud, the right-of-way.

¶ Then you must be able to give a loud commanding note, for emergencies or when the low note proves inadequate.

¶ The continual use of the loud note for all service, makes unnecessary noise, lessening the commanding effect of the emergency note by making the same unduly familiar when occasion does not require its use, invites adverse legislation and, last but not least, makes an excessive waste of battery current.



¶ Common sense, laws and ordinances, say to you that the low note must be retained.

¶ Until the advent of the TUTO Horn, with its complete signalling service, it was necessary to retain the bulb horn as the mild signal, despite its inadequate note and its insufficient means of operation.

¶ To-day the TUTO Horn is acknowledged by the most discriminating motorists, leading engineers and up-to-date sales departments as the only warning device that will do all of the signalling of the car in a most simple and safe manner.

¶ The TUTO Horn produces a low note which is effective fully 90% of the time and more adequate than the bulb horn, by an ordinary pressure on the operating button. Fully depressing this same button, gives the loud emergency signal, and there is no thought or extra movement of the hands required to go from the service to the emergency signal.

¶ What could be more effective and positive than the TUTO method of operation? The TUTO Horn comes complete with everything necessary to make a most permanent and neat installation on any type or make of car, and retails for $25.00 in any finish with a long or short projector.

NET SALES GAIN 211 PER CENT.
over corresponding ten months of previous year.

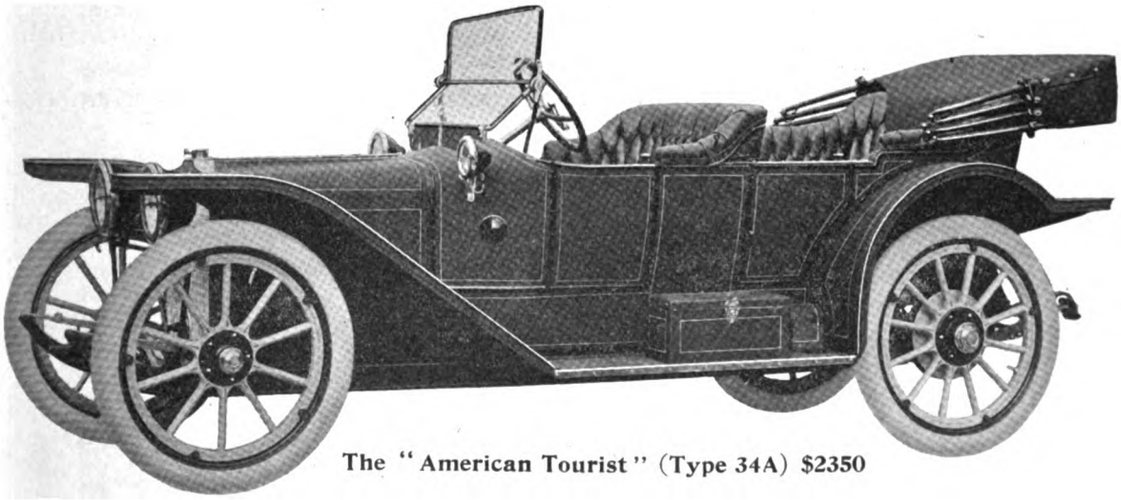
Electrically Lighted
Self-Starting

NOT SILENT—but "a noise so faint one scarce distinguishes it from silence."

AMERICAN
UNDERSLUNG

IN the trade journals of the week of June 16th we made the announcement of the "American Underslung" line for 1913. We cited the phenomenal increase in sales of 211 per cent. in the past ten months over the corresponding period of a year ago. We reiterated our statement that the "American Underslung" is destined the final construction in motor cars.

We have evidence of our foresight. Our sales offices are deluged with inquiries. These come not only from the dealers. Hundreds of motorists have written us. This is undisputable testimony that the "American Underslung" will be a power in automobile evolution in 1913.



Now is the time for dealers to cash in on this rush to the *final type* in automobiles. We have enlarged facilities for taking care of this demand. We foresaw it. We are prepared.

The "American Underslung" differs in constructive principle. *The frame—the very backbone of the car—is slung under the axles instead of being placed over the axles.* The low center of gravity means SAFETY and added comfort; straight line drive means *less wasted power;* larger wheels mean easier riding, tire economy and *maximum road clearance.*

For the season of 1913 we announce our three famous standard models: the "American Traveler" (Type 56A), at $4500; the "American Tourist" (Type 34A), $2350; the "American Scout" (Type 22A), $1475, all fully equipped.

Write us for a handsome 1913 catalogue and a simple treatise an the "Advantages of Underslung construction."

American Motors Company
Dept. E, Indianapolis, Indiana

The "American Tourist" (Type 34A) $2350

Four passengers. Motor, four cylinders, 4 1-2-inch bore, 5-inch stroke; Wheel base 118 inch; tires, 37 x 4 inch; front and rear on Q. D. demountable rims.

$2350 includes regular equipment as follows; electric light dynamo outfit complete with generator and storage battery supplying five lamps. $50 Warner speedometer; fine plate glass wind shield; Disco self-starter; fine mohair top and curtains; high tension magneto and storage battery; one extra rim; shock absorber; robe rail: horn; jack, tool and tire repair outfit.

ASK "HAYES" ABOUT YOUR SHEET METAL PROBLEMS

ON TIME

"On Time" are the two best words in the English language to the automobile manufacturer who, in the headlong rush of his busy season, is constantly fearing a holdup in bodies, fenders, or sheet metal work of any kind.

The Hayes enormous new plants and perfected system may be relied upon to produce the goods on the date specified. Furthermore, these goods will always be standardized and interchangeable. Hayes workmanship insures that.

The tremendous growth of the Hayes plant indicates the extent to which manufacturers are depending upon Hayes to "beat up" their own output. They find it a big advantage to have their fenders (fully enameled) brought into their factory completely assembled with fender irons and running boards ready for quick attachment, and at a price much lower than they can possibly do the work themselves. And the same is true of every sheet metal part that goes onto an automobile.

Manufacturers are finding out that it saves money and much valuable factory space to turn their blue prints over to the Hayes organization, and get their all-metal or wood-metal bodies delivered fully equipped with fenders and running boards.

It is the cheapest and most efficient method to double up production and deliver "ON TIME."

Hayes high-standard of quality and workmanship have never been questioned. In order to insure quick delivery, get your specifications in early.

Bodies	**Fenders**
Running Boards	**Shields**
Aprons	**Mufflers**
Dashes	**Shrouds**
Tool Boxes	**Battery Boxes**
Gasoline Tanks	**Prest-O-Lite Boxes, Etc.**

Everything in sheet metal for the automobile.

1/4 MILLION

EXHAUST TUBES IN TWELVE MONTHS

We made this enormous quantity because we received orders for them. We received orders for them because we can make them better, cheaper and quicker than any one else.

We make them better because we have the most up-to-date machinery and employ only expert workmen.

We make them cheaper because we make our own tubing and make so many.

We make them quicker because we know how to make them and do not fuss, fret or fume if the job is new or a "sticker."

Our tubes are strong, accurate to dimensions and very light in weight.

It is not foolish to make your own tubes, but it's futile, especially when you can get what you want without wandering.

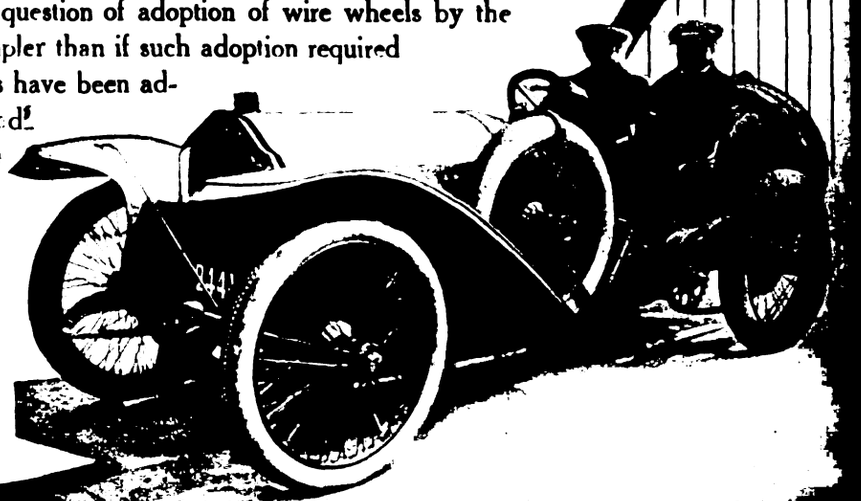
World's Greatest Racing Drivers Are Converts to Wire Wheels.

Hemery, the great driver, who has shone so spectacularly in this country in Vanderbilt races and in recent Grand Prix races, uses wire wheels on his present car, the Lorraine-Dietrich, which is shown herewith. Among others who are also converts to the wire wheel are Sizaire, Hanriot, Bablot, and many others less well known in this country.

This fact, and the simple showing of about 80% of the recent Grand Prix racing cars being equipped with wire wheels, means only one thing, the absolute supremacy of wire wheels.

Wire wheels mean greatly increased tire life (68.75% is the actual figure of extra tire mileage on wire wheels over wooden wheels as a result of a six months' test conducted at the English Daimler factory).



70% MORE TIRE MILES

WIRE McCUE WHEELS

Wire wheels mean more tire life, first, because they dissipate the excess of heat generated by the friction of driving; while wooden wheels being non-conductors of heat hold this heat within the wheels of the tires and the process of devulcanization takes place.

Wire wheels increase your tire life, in the second place, because of their greater flexibility. When a tire, mounted on a wire wheel, strikes a stone, the crushing force on the tire fabric is not nearly so great as though that same tire were mounted on a wooden wheel. The comparison is the same as striking your fist against a punching bag as compared with striking it against a solid stone wall.

The fact that McCue Axles admit of the use either of wire wheels or wooden wheels on the same spindle makes the question of adoption of wire wheels by the American manufacturer far simpler than if such adoption required special design. McCue Axles have been admittedly leaders for some time and now this latest improvement whereby they may be used for either wire or wooden wheels places them in a class by themselves.

Little Six—Model 46

The Car They Are All Talking About

Embodies the most advanced American and European ideas of approved design and construction.

A distinctive car of unusual power, quietness, comfort and style.

"It's the Car You've Been Waiting For"

- 6-cylinder motor, 4⅜" bore x 5½" stroke, A. L. A. M. rating 46 H. P.
- 130" wheel-base, 37 x 5" tires.
- Handsome V-shaped radiator.
- Silent chain-driven cam and magneto shafts.
- Option on right or lefthand steering control.
- Exceptional quietness in operation.
- Attractive straight line body designs with concealed locks and hinges.
- Clean running boards.
- Self-starter on motor.
- Dynamo lighting system.
- Unequaled riding qualities.
- Economical in operation and upkeep expense.
- Beautiful appointment and finish in optional colors.

Price with Standard Equipment on all Open Type Bodies.....$4350
Price with Standard Equipment on all Limousine Type Bodies.....$5350

THE MOTOR WORLD

Vol. XXXII New York, U. S. A., Thursday, July 18, 1912. No. 4

GROUT AGAIN IN RECEIVER'S HANDS

Old Company Unable to Weather Death of Two Officials and Other Adversity—Its Recovery Doubtful.

For the second time in its troubled existence, the Grout Automobile Co., of Orange, Mass., is in the hands of a receiver. R. T. Shumway, a business man of that city, has been appointed by the Federal court to take charge of the plant, with authority to operate it temporarily. It is believed, however, that the financial condition of the company is such that it is not likely to recover from its embarrassment and that the property will be offered for sale.

The Grout company grew out of the sewing machine business of W. L. Grout, which was operated for several years by the Grout brothers, who first produced steam cars but later turned to the gasolene vehicle. Several years ago the business became financially involved, at which time E. S. Hall, an Orange lawyer, was appointed one of the receivers. In due course he organized the present company, which was capitalized for $100,000, of which John W. Wheeler became president, Hall himself assuming the office of treasurer. Walter Gould was vice-president and sales manager and George P. Dexter was the secretary.

Wheeler and Gould died soon after, and the brunt of the burden fell on Hall, who was more versed in law than in automobile affairs. The capital also proved insufficient, and the combined handicap proved so great that last week a receiver was applied for.

Splitdorf Begins Removal to New Jersey.

Removal of the plant of the Splitdorf Electrical Co. from New York City to Newark, N. J., commenced late last week, one of the several factories comprising the plant already being practically vacated. The equipment of the other buildings will be removed at opportune moments, but it is unlikely that the removal will be completed before September 1st; until that time, at least, the offices remain in New York. In Newark the Splitdorf plant will be concentrated in the building heretofore occupied by the Eagle Co., which is controlled by John F. Alvord, who acquired the controlling interest in the Splitdorf company, some two months ago. The Eagle Co., which manufactures marine engines and spark plugs, has been removed to Torrington, Conn., where other of Alvord's enterprises are located. When the removal of the Splitdorf plant to Newark is completed, a splendidly appointed service station will take its place in New York.

Brown Forms Another Truck Company.

While still retaining the presidency and general management of the Mais Motor Truck Co., of Indianapolis, Will H. Brown has organized the Brown Commercial Car Co., in Peru, Ind. Associated with Brown in the enterprise are several prominent automobile men and other residents of Peru, whose names for the present will not be disclosed. Brown will be president and general manager of the new company, which will produce a light four-cylinder truck of special design and incorporating several special features worked out by Brown himself. Its sales offices will be located in Indianapolis. It is stated that the Mais Motor Truck Co. is undergoing reorganization of some sort, but Brown will say nothing regarding it.

Oldfield Patent Bill Practically Dead.

Despite the strenuous efforts of the author of the Oldfield bill, which sought more or less to revolutionize the patent system in this country, Representative Oldfield himself admits that it will be impossible to induce the present Congress to pass his act or any other patent legislation. The Oldfield bill aroused widespread opposition, and its failure to make progress will cause no surprise. Mr. Oldfield, who is chairman of the House Committee on Patents, has not been able to induce his own committee to report his measure.

RESHAPING UNITED STATES MOTOR

Brush Runabout and All Two-Cylinder Models to be Discontinued but No General Upheaval in Prospect—Things Achieved and in View.

Beliefs that prodigious upheavals will follow the entry of the banking interests into active participation in the management of the United States Motor Co. are not likely to be borne out. Beliefs of the sort have given rise to such printed utterances that Benjamin Briscoe probably would retire from the presidency of the big corporation on August 1st next and that the Columbia plant would be removed from Hartford, Conn., to Dayton, Ohio, and consolidated with the Stoddard-Dayton plant, to mention but two of a number of somewhat similar instances.

As a matter of fact, the company is working out its problems in its own way, and while more or less internal reorganization will result, it will simply serve to more firmly intrench it in its position. There is no foundation for the reports that Briscoe will retire or that the Columbia plant will be removed to Ohio, nor will there be any general exodus of officials or employes or any far-reaching concentration of plants or models.

The Gray Motor Co., of Detroit, which made marine engines, has been resold to its original owners, and among other matters which have been definitely settled are that the manufacture of the Brush runabout will be discontinued, or practically discontinued, at any rate. Hereafter, it will be made only to meet immediate demands. Whether the Brush plant will be offered for sale or be used for other purposes remains to be decided. It is also settled that the manufacture of the two-cylinder Maxwell models will be discontinued, which means that hereafter the United States Motor Co. will have to do only with "fours" and "sixes." While the prices of the Brush runabout, $350 and $450, made it appear attractive and

Digitized by Google

a limited demand still exists for two-cylinder cars, their manufacture has not proved profitable. Generally speaking, the public will have little, if anything, to do with other than "fours" and "sixes," and the United States company purposes to recognize the fact and to shape its productions accordingly.

The report that the Columbia factory would be removed to Dayton was published in conspicuous fashion in the Dayton papers, but it had no more basis in fact than that A. C. Mertens, superintendent of the Columbia factory, has been transferred to the Stoddard-Dayton plant and assumed charge thereof. The vacancy in Hartford caused by his transfer has been filled by appointment of C. J. Jamison, who has been designated factory manager of the Columbia plant; he previously was assistant in charge of manufacturing of the United States company, with headquarters in New York City.

None of the men conspicuous in the management of the company are slated to retire. The only one who has retired is Horace De Lisser, one of the vice-presidents, who has rejoined the Ajax-Grieb Rubber Co. With Alfred Reeves, one of the other vice-presidents, De Lisser shared the sales management of the big corporation. His retirement leaves the sales department entirely in Reeves's hands and with undivided authority, and with Reeves's undoubted ability and equally undoubted affability, good results are practically certain to follow.

The reconstruction of the United States Motor Co. is progressing satisfactorily, something like 90 per cent. of its creditors have agreed to the 90-day extension; practically the only objectors are comparatively small creditors, whose actions will not in any way disturb the progress of affairs. The 90-day period expires September 15th next, when it is probable that the refinancing plan now being worked out by the banking interests will be ready for adoption. So far as can be learned, it provides for a reduction of the company's capital from $42,000,000 to $25,000,000, which, in the words of a man high up in the company's affairs, "will represent exactly what we are."

Whatever plan may be adopted, it is certain that certain New York capitalists are so heavily interested in the company that it can be and will be carried through any storms. Its temporary stringency was due to the too common failing of overextending itself. As expressed by an official source, the company sought to do a business of $25,000,000 a year when it should have done about $18,000,000. The "forcing" that resulted in so many directions did not work out satisfactorily, particularly as the months of March and April were almost abnormal from the weather standpoint and made a quick turnover impossible. As it was, the company owed $7,000,000 in March before its goods really began to move, but it operated to such good advantage that by the first of June its indebtedness bad been reduced to $2,600,000.

London Hears of American Combination.

According to a report from London, "preliminary negotiations are well planned" for a combination which will include the Hudson, Franklin and the American Fiat gasolene cars, the Anderson electric and the Commer truck, the report adding that "at present the matter is being handled principally in London." On this side of the water little or nothing is known of the proposed combination. Representatives of at least two of the companies named state that they have heard something of such a movement but they take small stock in it. The others mentioned declare they know nothing about such negotiations. The fact that R. D. Chapin, president of the Hudson Motor Car Co., has been in England for several weeks, suggests that he may have a hand in the matter, but at the Hudson factory in Detroit it is denied that the company has any intention of entering such a combination.

Willys to Take Over Garford August 1st.

While John N. Willys has consummated the purchase of the Garford Co., of Elyria, Ohio, the actual transfer of the Garford property will not take place until August 1st. Meanwhile all of the common stock which Willys purchased will be deposited in a Cleveland trust company. When the transfer is completed the Garford officers and directors will resign, of course, and Willys and his lieutenants will step into their places. It is probable that the name of the company will be changed to the Willys-Garford Co., and that the title of the Gramm Motor Truck Co., of Lima, Ohio, which Willys purchased some three months ago, similarly will be changed to the Willys-Gramm Co.

Rushmore's Foreign Interests Reorganized.

Rushmore Lamps, Ltd., is the title of a new organization which has taken over the London business of the Rushmore Dynamo Co., of Plainfield, N. J. The business will be carried on at the old address, 46 Brewer street. The new company is capitalized at £20,000, made up of 7,500 6 percent cumulative preferred shares and 12,500 shares of common stock, all of £1 par value.

Bank Gets Judgment Against Dealer.

The Almy Motor Car Co., Walter A. Almy and Elizabeth Almy, of White Plains, N. Y., are debtors in two judgments filed this week in the New York county clerk's office by the First National Bank of White Plains. The judgments are for $780.84 and $882.57. The Almy company handles automobiles and maintains a rather imposing store.

Imperial Secures Another Jackson Plant.

The Imperial Automobile Co. of Jackson, Mich., on Thursday last acquired the former Buick plant in that city. The building acquired will add 350,000 square feet of floor space to the Imperial facilities and permit of the employment of 800 additional men. It will also permit the Imperial output to be increased to 8,000 cars per year.

Cooper Hewitt Sues General Electric.

The Cooper Hewitt Electric Co., of New York, has entered suit in the United States District Court for the Southern District of New York against the General Electric Co., of Schenectady, N. Y., for alleged infringement of patent No. 1,030,262, which is described in the patent specifications as "In a gas or vapor apparatus, the combination of two electrodes, a starting electrode, and a means for connecting the starting electrode with, and disconnecting it from, one only of the working electrodes." Briefly, the patent covers a variation of the principle upon which both the Cooper Hewitt mercury vapor lamp and the mercury arc alternating current rectifier are built, and was issued on June 18th, last.

Ford Planning Output of 150,000 Cars.

Henry Ford, president of the Ford Motor Company, sailed for Europe on Saturday last, accompanied by his family. He will be absent about six weeks.

Despite somewhat lurid reports to the contrary, Ford carried with him no idea of producing 250,000 Ford cars for the 1913 market. He is, however, actually planning an output of 150,000 cars. Apparently when this figure got abroad some ready reckoner found it easy to add a mere trifle of 100,000 cars to the Ford estimate.

Tire Filler Man Sails to Europe.

Growing out of a number of inquiries from foreign sources for the products of his company, A. H. Spiegel, who is secretary and treasurer of the Essenkay Co., of Chicago, Ill., which manufactures a tire filling compound, has sailed for Europe. He will remain abroad for several weeks.

Boulade Visits American Zenith Plant.

A. Boulade, general manager of the French Zenith company, is paying a visit to America. He is spending most of his time with the Zenith Carburetter Co., of Detroit, which, incidentally, has recently increased its capital stock from $10,000 to $30,000.

Studebaker Retires Block of Stock.

In accordance with the provisions of its charter, the Studebaker Corporation, of Detroit, Mich., has taken up and canceled $405,000 of its preferred stock issue. For the purpose, part of its profits for the fiscal year ending December 31, 1911, were used.

Ottomobile Acquires Factory in New Jersey.

The Ottomobile Co., of Philadelphia has acquired what was formerly the Alcott Foundry building in Mt. Holly, N. J., and is preparing to take possession. Part of the machinery already has been removed to the New Jersey address.

DAIMLER LICENSES ARE AVAILABLE

Despite Recent Transactions, Others Will be Afforded Opportunity to Use its Patents—Three that Reach Far.

Until the consummation of the recent deal whereby the Daimler American rights, so far as they apply to commercial vehicles, were conveyed to the General Vehicle Co., of Long Island City, N. Y., and the rights for pleasure cars to a New York syndicate, which has not yet completed its organization, it is known that the Daimler Mfg. Co., of New York, which previously held all rights, was near to instituting a campaign of patent litigation. The matter had been placed in the hands of a prominent New York legal firm, and suits were in preparation, most of them, it is understood, being based on the Daimler change gate patent.

It is by no means certain that such intentions have been entirely abandoned, but apparently the recent transactions have served to somewhat alter the situation, and before instituting legal proceedings, to which they are adverse, the respective owners of the Daimler American rights will accord those who desire and who are considered worthy, licenses to operate under the several patents. These include not merely the change gate patent, but patents covering the Mercedes type of radiator and the flywheel fan, all of which the Daimler interests claim to control absolutely. Several parts manufacturers are said to be already negotiating for such licenses.

As the deal with the General Vehicle Co. bears date of June 18th last, all alleged infringers of the Daimler patents prior to that date are responsible to the Daimler Mfg. Co., of New York, but such licenses as may now be granted covering commercial vehicles will be issued by the General Vehicle Co.; all other rights still are controlled by the Daimler Mfg. Co., of New York, which was organized in 1899 by William Steinway, and which, since fire wiped out its plant in Long Island City several years ago, has not been in active operation, although it has still retained corporate existence.

Weed Scores Point in Appellate Court.

After considerable litigation, the justices of the United States Circuit Court of Appeals for the Sixth Circuit, in Cincinnati, O., Monday last, July 15th, dismissed the amended and final petition of the Atlas Chain Co. and the Perry Chain Grip Co. to intervene as defendants in the suit brought under the Parsons patent, No. 723,299, by the Weed Chain Tire Grip Co. against Dorsey E. Foote, of Cleveland, who was handling tire chain grips made by the Atlas and Perry companies. A preliminary injunction was issued against Foote last December, and in March of this year a motion made to dissolve the injunction was denied; thereupon an appeal was taken from the orders granting the injunction and denying its dissolution. In the Court of Appeals the Perry and Atlas companies filed the petition for intervention, alleging that they practically were defendants, having undertaken the expenses and defense of the suit. This petition was denied some time ago, but was renewed in amended form only to be denied again. Meanwhile, Foote, who traded as the D. E. Foote Rubber Co., has gone into bankruptcy.

Losey Rejoins Durant in Republic.

Although W. C. Durant is not yet ready to make known the names of the men who are associated with him in his new $65,000,000 Republic Motor Co., of Delaware, it is known that at least one of his lieutenants will be R. H. Losey, who has been appointed general sales manager of the Republic Motor Co. of New York, which is one of the ten similar companies in process of formation in as many states and which will go to make up the parent Delaware corporation. For the past four years Losey has been the head of the Indian branch of the Buick Motor Co., his connection with that company dating back to 1904, when, under Durant, who then was head of the company, he became one of its traveling representatives. In 1908 he was advanced to the managership of the branch, which position he has held up to the present time.

Former New Yorker Heads the Perfex.

The Perfex Co. of Los Angeles (Cal.), which recently launched its first car, has completed its organization by the election of the following officers: President, Paul Smith, formerly of New York; vice-president and general manager, James Fouche; secretary and treasurer, O. B. Hutchings; sales manager, J. B. Marrow. The company's plant is located at 126 East Jefferson street, Los Angeles, where 100 Perfex cars will be turned out during the current year. The car is of Fouche's design.

Crescent Air Starter Chooses Officers.

The Motor Appliances Co., of Detroit, Mich., which controls the patents under which the Crescent air-starting system is manufactured, has elected the following officers: President, Floyd W. Owen; vice-president, Edward T. Birdsall; secretary-treasurer, Frank Sturgis. In addition to these officers, the directorate comprises H. Stevenson, A. Brett Road, Charles Milne and John Lane.

Halliwell Acquires Stewart Gas Savers.

The Halliwell Co., of Los Angeles, has acquired the selling rights to the Stewart piston gas saver, made by the A. C. Stewart Machine Works, of Los Angeles, which also manufactures the Stewart carburetter. The transaction, it is stated, involves a contract for 90,000 of the fuel-economizing devices.

SIZZLING CHARGES AGAINST SEITZ

Applying for Receiver, Stockholder Alleges Varied Misdoings, Including Fake Books—Wants Directors Enjoined.

Charging gross mismanagement and alleging, among other things, that "an imperfect, incorrect and fraudulent" set of books has been intentionally kept and that certain property has been sold and a part of the proceeds diverted to the pockets of individual directors, Frank H. Carpenter, a stockholder, has applied to the Circuit Court of Wayne County, Mich., for the appointment of a receiver for the Seitz Automobile and Transmission Co., of Detroit, whose plant is located in Wyandotte, Mich.

Carpenter's complaint fairly breathes fire. He is the holder of $6,000 worth of Seitz stock, the par value of which is $10 per share, on which he states no dividend ever has been paid since the incorporation of the company in 1907. Instead, he represents that during the six months preceding December 1, 1911, there was a net loss of more than $18,000, due to alleged "gross mismanagement and fraudulent transactions." In addition to asserting that a fraudulent set of books has been kept for the last two years, Carpenter states that William J. Seitz, the president of the company, and his brother, John O. Seitz, have spent large sums of money in traveling, for which no accounting has ever been made, although often requested. The Seitz factory was closed from December 1st, 1911, to June 1st, 1912, during which time, Carpenter charges that the officers and directors paid to themselves large salaries. He states that since it was reopened, only five or six men have been employed and that they are merely assembling the material on hand, and that it is the intention of the officers and directors to close the plant as soon as this work is accomplished. He also declares that on January 13th last they sold to themselves property of the company valued at $31,000 for the sum of $31,500, of which the company received $21,000 in cash, the remainder being paid in stock owned by the directors involved. He specifically names Frank Marx, of Wyandotte, one of the directors, as having received $5,000 from the proceeds of this transaction.

On May 4th last he claims that the directors mortgaged other property for the sum of $18,000, and that the mortgage was executed by Frank Marx, August Loeffler, H. C. Woelmer and S. A. Kring, all of whom were officers and directors of the company. at the time of the transfer. This mortgage falls due one year from its date, when Carpenter states it is his belief that it is the intention of the directors to foreclose it, thereby excluding the stockholders from participating in any of the proceeds.

Previously, he alleges, another parcel of

Digitized by Google

property which in 1907 was purchased for $12,560, was sold for $9,000, of which sum $5,000 was applied on the mortgage and the remainder of $4,000 turned over to the treasurer of the company, for which no accounting has been made.

In applying for the appointment of a receiver to conserve the property and wind up the company and to distribute the profits equitably, Carpenter asks that suits be instituted against the directors to recover the property and moneys involved, and that the directors be enjoined from selling the mortgaged property until an accounting shall have been rendered.

Taxicab Promoter Jailed for Theft.

Troubles have not come singly to George Lapp, of Jersey City, N. J., for, following suit for money owing by the Hudson City Auto Exchange, of which he was backer, and which nursed a taxicab scheme, he has been arrested and sentenced to serve from one to seven years in the New Jersey State Prison on the charge of stealing an automobile valued at $6,000 from a citizen of Newark. When Lapp first got back of the automobile exchange he stated to the Diamond Rubber Co. of New York that he would vouch for bills up to $2,000; so when the amount ran a trifle in excess of this figure the company, failing to collect, sued Lapp and was awarded judgment for $2,000; the rubber company then applied for a receivership for the concern, and one was appointed. The alleged theft occurred about the same time, and Lapp's troubles had their culmination on Friday last, July 12th, when Judge Martin, in the Court of Special Sessions in Paterson, meted out the sentence. Lapp's difficulties may be said to have been of simple origin, for before the exchange company was formed he confided in a friend that he was disgusted with the trolley service and thought there were enough more like himself to make a taxicab service profitable.

Locomobile Mortgages to Secure Bonds.

To carry out the plan of refinancing of the company, which was given in detail in the Motor World of June 6th, the Locomobile Co. of America, of Bridgeport, Conn., has filed a mortgage on its property to the amount of $1,500,000. The mortgage was taken up by the Bankers' Trust Co. of New York and will be used to secure the issue of 10-year 6 per cent. sinking fund bonds, for which the refinancing plan provides.

Corset Maker Gets Economy Truck Plant.

After two previous offers had been rejected, the creditors of the bankrupt Economy Motor Car Co., of Joliet, Ill., have agreed to the sale of the factory buildnig to a corset manufacturer for $14,649.66. Former officers of the embarrassed company sought to acquire the plant and employ it in the production of a popular-priced electric vehicle, but their offer was considered insufficient and was refused.

LAW'S DELAY MAY TERMINATE SUIT

Proceedings Involving Agency for Havers Car Develop Unusual Phase—Botto Succeeds in Opening Default.

Lack of despatch in the Supreme Court for New York county may or may not put a fiasco-like finish to the suit which was brought some two months ago by the Havers-Imperial Auto Sales Co., of 1662 Broadway, New York, against William M. Botto, of the Knickerbocker Motor Car Sales Co., of 1634 Broadway, to establish the true ownership of the agency in New York and vicinity for the Havers cars. The complainants in the action sought to rush it along through and get some sort of ruling on their motion for a preliminary injunction restraining Botto and his concern from handling the Havers line, but inasmuch as the Havers contract in question will die a natural death next month, there now are indications that before the ownership can be adjudicated there will be no contract to be owned. In that case, the Imperial company may continue the litigation, asking as damages the profits made by the Botto faction between the time of the business rupture and the expiration of the contract.

The Havers trouble, as the Motor World previously reported, began when Botto broke away from the Havers-Imperial concern, which claimed it was formed to handle the Havers, upon the promise that Botto would secure the contract, but shortly before the action was commenced the Havers business appeared lower down the Great White Way under the signboard of the Knickerbocker concern, in which Botto and one Edward F. Rush were prime movers. Uncomplimentary statements were bandied and legal horns were locked. Botto defaulted in answering the motion for a preliminary injunction, and the judge has as yet made no decision; several times Botto attempted to get leave to put in his delayed answer, and Tuesday of this week, when no opposition was offered, the judge gave him this permission. The whole matter now hangs on the decision and the time it is handed down.

Ideal Surrenders West Virginia Charter.

Having incorporated as an Indiana corporation, with $100,000 capital stock, the Ideal Motor Car Co., of Indianapolis, maker of Stutz cars, has surrendered its West Virginia charter. In obedience to the law, the West Virginia corporation has filed notice of its withdrawal from Indiana and revocation of its appointments of agencies.

Everitt and Flanders Lease a Building.

Although the "changes in the fortunes" of the Everitt Motor Car Co., of Detroit—as the situation was officially described—which was to result in the merger of the Everitt company and the Flanders Mfg. Co., has been deferred for good and sufficient reasons, the cordial relations and the understanding existing between the two corporations, has taken form in the joint lease of a new building in Detroit, which both will occupy as their sales rooms and business offices. The building, which is not yet wholly completed, is located at the corner of Warren and Woodward avenues, which is 125 x 150 feet.

Cole Establishes a Branch in Omaha.

The Cole Motor Car Co., of Indianapolis, Ind., has located a branch at 1102 Farnam street, Omaha, Neb. It will be in charge of E. E. Butler, but C. J. Corkhill, district sales manager, also will make his headquarters there. Both men have served terms on the selling forces of both the Olds and Apperson companies.

Crum Becomes a Kansas Manufacturer.

C. J. Crum, of Ottawa, Kans., who formerly sold the goods for a Lawrence (Kans.) concern, has acquired the business of manufacturing a carbon remover, a radiator anti-leak and several other automobile specialties. He will remove the business from Lawrence to Ottawa.

Milwaukee Plug Maker to Build Factory.

The Milwaukee Auto Specialty Co. of Milwaukee, Wis., maker of Victor and Centerfire spark plugs, has let contracts for the erection of a two-story building, 36 x 40 feet, at the corner of Seventh and Chestnut streets. It will represent an expenditure of $10,000.

National Malleable's President Killed.

John J. Manning, president of the National Malleable Castings Co., of Toledo, Ohio, was instantly killed at midnight on July 13th, when his automobile crashed into a street car. Manning, who formerly resided in Cleveland, was in his 56th year.

R. C. H. Opens Branch in Newark.

The R. C. H. Corporation, of Detroit, has established a factory branch in Newark, N. J., at 32 Halsey street, where both R. C. H. gasolene cars and Hupp-Yeats electrics will be handled. The branch is in charge of A. W. and W. R. Christopher.

Studebaker Opens Second Texas Branch.

To better meet the pressing demands of Southern Texas, the Studebaker Company of Texas, whose headquarters are in Dallas, has established a branch and warehouse in San Antonio. It is in charge of C. W. Hartman.

Tuttle to Quit Cars to Make Parts.

Harry Tuttle, service manager of the Dayton-Motor Car Co., Dayton, O., has resigned that position, his resignation becoming effective August 1st. Tuttle has in view the organization of an automobile parts company.

New York, N. Y.—William C. Reynolds, Inc., under New York laws, with $3,000 capital; to deal in motor cars. Corporators —Charles W. Reynolds, 188 Wadsworth avenue; Rene Dequet, 105 West 101st street; Otto Schiller, 53 West 63d street.

New York, N. Y.—American Motor Freight Co., under New York laws, with $25,000 capital; to operate a motor delivery. Corporators—Harry G. Waring, Yonkers, N. Y.; Harvey W. Bell, 301 Palisade avenue, Yonkers; Howard G. Phillips, 220 West 98th street.

New York, N. Y.—Amherst Auto Renting Co., under New York laws, with $5,000 capital; to rent and deal in motor cars. Corporators—Peter V. Hoyt, 226 West 97th street; Daniel J. McAndrews, 141 West 96th street; George Schippereit, 177A 31st street, Brooklyn.

Changes of Corporate Names.

Toledo, Ohio—Rassel Motor Car Co. to Toledo Motor Truck Co.

Lexington, Ky.—Bayliss Motor Car Co. to Central Motor Car Co.

Cleveland, Ohio—Weaver-Sealand Motor Co. to Weaver-Twelvetree Motor Co.

Recent Losses by Fire.

Allenhurst, N. J.—Harry Content, garage destroyed. Loss, $13,000.

Milford, Mass.—N. L. Huff, garage and five cars restroyed. Loss, $15,000.

Peaceful Valley, Wash.—Spokane Cab Co., 1647 Walter avenue, garage and several cars destroyed.

Houston, Tex.—J. W. Davis, Milam avenue, carriage and automobile repair shop damaged. Loss, $700.

Boston Will Repeat Its Truck Show.

Although its inclusion in the N. A. A. M. national circuit made certain that Boston would stage its pleasure car show in 1913, no such assurance attached to the commercial vehicle show which the Boston Automobile Dealers' Association inaugurated this year. The association, however, this week announced that the truck show also would be repeated. As heretofore, both shows will be staged in Mechanics Building, the pleasure cars holding forth during the week of March 8-15, inclusive, and the trucks, under the auspices of the Boston Commercial Motor Vehicle Association, Inc., being exhibited during the week of March 19-26. Chester I. Campbell again will manage both functions.

"DOUBLE" CONCERN MUDDLES CASE

Business as Corporation and Co-partnership Causes Judges to Disagree—However, Suit Must be Retried.

The somewhat interesting and peculiar existence of Sewall & Alden, of New York City, insurance agents, both as a corporation and a co-partnership, which was nearly but not quite sufficient to disrupt opinion in Supreme Court for New York County in an action brought by the Renault Freres Selling Branch, Inc., to recover the price of a repair job, has proven the basis for a divided opinion in the Appellate Division. Whereas the jury in the lower court gave the Renault company a judgment for $2,051.88 and the judge denied a motion for a new trial, three of the five justices of the Appellate Division, on Friday last, July 12, reversed the judgment and directed a new trial, while two dissented.

The whole trouble followed an accident to a car owned by one Schuyler V. C. Hamilton, who carried accident insurance with the General Accident, Fire and Life Assurance Corporation of Perth, Scotland, represented in New York City by Sewall & Alden, but whether by the corporation or the co-partnership is a point in dispute. The Renault side of the case is that one Grassmuck, who was supposed to represent Sewall & Alden and who was an insurance adjuster, agreed to an estimate of repairs and said that Sewall & Alden would pay the bill. Another phase of the insurance agents' status is revealed in the opinion ordering reversal wherein it is said, "Grassmuck further testified that on other occasions in adjusting losses he signed the name 'Sewall & Alden, Managers' and that he intended so to sign in this case, and according to his recollection so dictated the letter, but that he signed it hastily and without examining it carefully and the word 'managers' was omitted." These judges, Laughlin, Ingraham and Scott, hold that the corporation "had nothing to do with procuring this insurance and had no interest therein or relation with the insurance company. . . . Grassmuck was not in the employ of the defendant and had no authority to represent it."

The dissenting justices, McLaughlin and Clarke, entered into the moral phase of the matter and in their vote for affirmance said, "It is conceded in the prevailing opinion that it does not appear that the plaintiff, prior to making the repairs, was aware of the fact that Sewall & Alden constituted a firm and was engaged in the same business as the defendant (the corporation). If plaintiff did not know of the existence of the firm it is difficult to imagine upon what theory, in view of prior transactions, the defendant can here escape liability on the ground that the firm gave the order, and not the corporation. The prior transactions, as already indicated, consisted in defendant's having similar repairs made and paying the bills therefor. Honesty and fair dealing required the defendant, if the transaction in question were by the firm and not by the corporation, to so inform the plaintiff."

Penn Inaugurates New Plant and New Cars.

Having completed its removal from Pittsburgh and taken full possession of its new factory in New Castle, Pa., the Penn Motor Car Co. has considerably enlarged its line. Previously it devoted itself to the production of the Penn "30," but it is now producing six models: a 30-horsepower roadster at $1,000, a 30-horsepower touring car at $1,100, a 45-horsepower roadster at $1,350, a 45-horsepower touring car at $1,400, and a 45-horsepower semi-racer at $1,600, also a 30-horsepower delivery wagon at $1,250. The New Castle plant, which has a capacity of 10,000 cars per year, is an imposing structure which covers slightly more than five acres of ground The main building is 510 x 60 feet and attached to it are six wings, each 60 x 150 feet. The entire building is of steel, concrete and glass, there being 12-foot windows around the entire structure. P. J. Keeling, who was treasurer of the Penn Motor Car Co., under the old order of things, now is president and general manager of the concern, E. E. Gregg is secretary and sales manager, M. O. Crawford is chief engineer and H. P. Hardesty factory manager.

Judgments Follow Prest-O-Lite Dispute.

Judgments which, were they against a smaller and less financially sound company, might cause come concern, were filed this week in the New York county clerk's office against The Prest-O-Lite Co., of Indianapolis, Ind., by the John R. Keim Mills, Inc., of Buffalo, N. Y., but instead of causing any alarm the debtor in the case is preparing to dispose of the matter, as it is a part of litigation between the two companies. The Keim mills manufactured tanks for the Prest-O-Lite company, and a dispute arose over a bill, whereupon the former brought suit in the Supreme Court for Erie county, N. Y., and secured judgment for $789.04 and $843.23 costs. The Prest-O-Lite Company took an appeal and arranged to give a bond for any judgment secured in the final stage of the action, but a "slip" in the bond matter, which, however, is easily righted, caused the filing of the judgments as a matter of protection by the Keim concern, and New York county was chosen as the place of filing, as the Prest-O-Lite attorneys are located there, and therefore can easily handle the matter.

Gasolene May Touch 20 Cents per Gallon.

According to reports which are gaining currency, the Standard Oil price-raising program calls for an ultimate price of 20 cents per gallon, delivered at garages. The big company has advanced the figures monthly from nine to 16 cents.

A. J. McCutcheon has opened a garage in Branford, Conn.

Horn & Allen is the style of a new garage firm in Albion, Neb.

Andrew J. Caron, of Methuen, Mass., is to open a garage on Kirk street.

Elmer Gaylord will open a garage in Grand Junction, Ia.

C. L. Light, of Deep River, Ia., has sold his garage to Lee Jacobs.

P. L. Bewley, a Taft (Cal.) blacksmith, has added a garage to his shop.

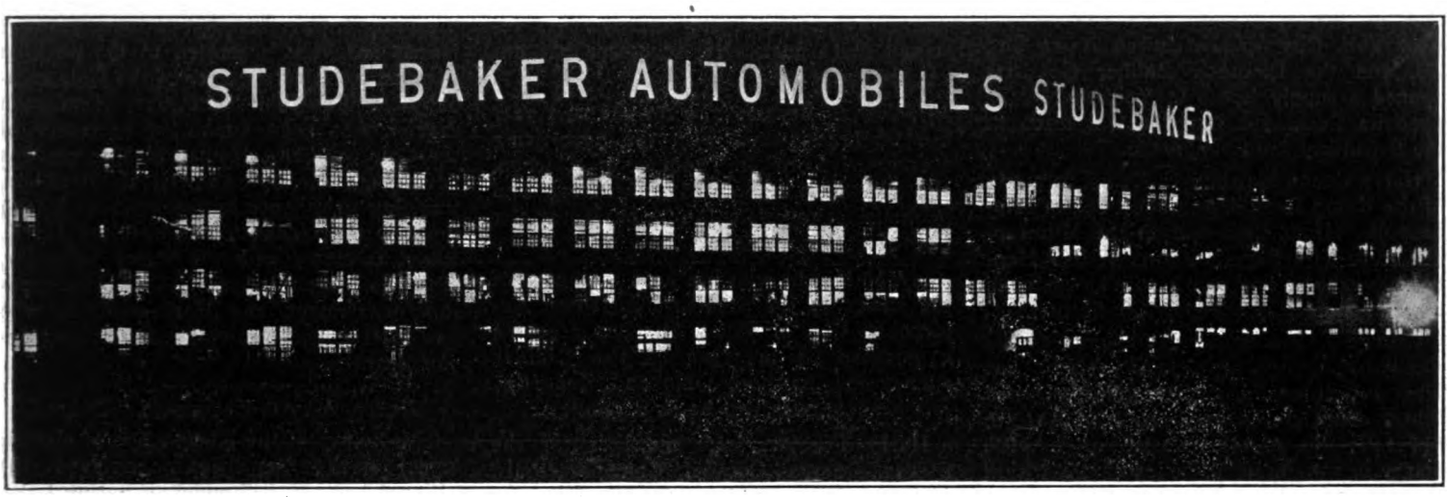
L. C. McCray is about to open a garage, 50 x 70 feet, in Gainesville, Fla.

in Eaton Rapids, Mich. It will be 40 x 70 feet and will be the second in the town.

F. L. Smith and G. Edwards are about to engage in business in Porterville, Cal.; they will trade as the Porterville Vulcanizing Co.

C. Parker Stearns, a former chauffeur, of Hartford, Conn., has taken the Ford agency for Andover, Gilead and Hebron, in the same state.

William Stockwell and George Kjos of Sherwood, N. D., have dissolved partnership as garage proprietors; the latter retains the business.



be located on Center street, near Fair Oaks.

Thomas E. Ward, of Sullivan, Ind., has purchased the interest of his partner, W. F. Ford, in the Ford Garage; the business has been moved to South Main street.

The Haas Building Co., of Los Angeles, Cal., has been granted authority to build a one-story garage at 184 Rose street; it will represent an expenditure of $6,000.

A. K. Lesher, a Reading (Pa.) restaurant proprietor, is to build a two-story garage, 40 x 100 feet, on Schley street, near Main; it will be of reinforced concrete and steel.

NIGHT VIEW OF THE STUDEBAKER PLANT ON THE DETROIT RIVER

The immense electric sign, which adorns plant 3, is 340 feet in length and the letters are 10 feet in height; 2,374 Tungsten lamps blaze nightly, current being furnished by a special generating set.

Charles Sherwood, in Watertown, Conn., has remodeled a barn into a garage.

Kirby & Hubbard, of Red Bank, N. J., are about to open a garage on Union street.

Arthur Brenneman and Joseph Ory are about to enter the garage field in Carlock, Ill.

John Pahnquist, John Footit and Charles Johnson are erecting a garage in Cromwell, Conn.

Z. K. Wright, of Lyons, Kan., has sold his interest in the Palace Garage to Edward Tobias.

Dundas & Gamble, of Riverside, Cal., are about to erect a two-story garage on Seventh street.

Charles A. Hastings is about to build a garage in Fitchburg, Mass. The Oakland agency will be a part of his business.

William P. Baldwin has opened an oxy-acetylene welding plant and repair shop at 56-58 East Water street, Chillicothe, O.

Frank Hamman is about to build a garage

The Joliet (Ill.) Auto Supply Co. is the style of a new concern in that town; Ben Moore, formerly of the Moore & Kickels Garage, is its manager.

G. L. Fenwick and H. Oyer have opened up in Marysville, Kan., at Ninth and Center streets; they will do business under the style Independent Garage.

Leon Bowen has secured permission to build a garage on Woodward avenue, between Ferry and Kirby streets, Detroit, Mich. It will cost $10,000.

W. M. and R. F. Wygant are building a garage at Central Valley, N. Y. They already operate a garage in Tuxedo Park, which is but a few miles distant.

Lavis Adolphson, formerly the proprietor of a garage in Springfield, Minn., has disposed of the business and is now connected with Kreitinger Bros.' garage.

Dr. Paul Deford, of Pasadena, Cal., is having plans prepared for a one-story brick commercial garage, 50 x 75 feet; it will

Earl Brown, formerly connected with the Davenport (Ia.) Auto Co., has branched out for himself under the style Brown Taxicab Co. His initial equipment is three cabs.

Permission has been granted to H. N. Moody of Peoria, Ill., to construct a one-story brick garage at 2006 Main street; it will represent an expenditure of $5,000.

A $10,000 garage, being erected at 102-4 Third street, Evansville, Ind., by David S. Bernstein, will be opened by Charles Jones of Indianapolis as soon as it is completed.

Benjamin L. Brundage, of Bakersfield, Cal., has secured permission to build a garage and storehouse at I and 15th streets; it will represent an expenditure of $4,800.

Arthur C. Kendall, of Pasadena, Cal., has taken the agency for Columbus Electric, Firestone-Columbus and Warren cars; he is temporarily located at 43 East Walnut street.

L. F. Hersh & Bro., wholesale grocers in Newark, N. J., are about to erect a garage,

Digitized by Google

50 x 125 feet, at Madison avenue and East Grand street, Elizabeth, N. J. It will cost $20,000.

City Auto Supply House is the style of a concern which has opened up in Harrisburg, Pa., at 119 Walnut street; E. L. Leinbach of New York City is the head of the company.

R. S. Carter, former manager of the Island City Garage, of Galveston, Tex., has taken the Correja agency for that state; he is temporarily located at 219 City Bank Building.

O. H. Wienges, of St. Matthews, S. C., and Cecil Culler, of Orangeburg, in the same state, are making ready to erect a garage in the former town; Culler will manage the business.

Shriver Bros., proprietors of the Mount Pleasant Garage, 1336-40 Thompson street, Harrisburg, Pa., have taken over the East End Garage; the change carries with it the Overland and Velie agencies.

T. J. Snyder, formerly a salesman in New York City for the United States Tire Co. and the Diamond Rubber Co., has opened a supply house in Yonkers, N. Y., opposite Park Hill Inn; he will trade as the Broadway Auto Supply Co.

Harry C. and Matthew C. Kemp, formerly of the Kemp Bros. Automobile Co., of Minneapolis, Minn., have bought the Minneapolis Auto Tire Repair Station at 1629 Hennepin avenue; the name will be changed to Minneapolis Tire Repair Co. Station.

George J. Batzey, doing business as the Economy Garage, in Pontiac, Mich., has filed a petition in bankruptcy in United States court in Detroit. His liabilities are $1,711.90; his assets consist of a $900 equity in a homestead, which comes within the exemption law.

The W. N. Hellen Motor Car Co. of Omaha, has entered the trade with the Firestone-Columbus agency for Nebraska and Western Iowa; W. N. Hellen, the principal in the new concern, has been connected with the automobile industry for several years.

The Texas Wagon Works, of Houston, Tex., has secured the Texas agency for General Motors trucks and will supply bodies to fit chassis; J. P. Beck, formerly connected with the Houston Motor Car Co., is manager of the wagon company's new department.

The Everitt Auto Sales Co., recently incorporated to handle cars of that name in Ohio, has opened up at 307-9 Mt. Vernon avenue, in Columbus. Its officers are: President, H. K. Dobson; vice-president, Elmer E. McConaha; secretary and treasurer, A. F. White.

Although the mooted merger of the Everitt Motor Car Co. and the Flanders Mfg. Co. has not yet come to pass, the "understanding" that exists between the two companies was exemplified last week when the Flanders branch in New York City was appointed agent for the Everitt car in the metropolitan district; its territory reaches as far north as Poughkeepsie and as far west as Pittsburgh.

The Whiting Motor Co., which maintains stores in New York City and Newark, N. J., and which handles the Mercer car in New York and New Jersey, has taken over the Mercer branch in Philadelphia, which hereafter will be operated as an agency at the old address, 620-622 North Broad street. The transaction gives to the Whiting people the Mercer representation for New York, New Jersey, Pennsylvania, Delaware and Maryland.

Changes Among Prominent Tradesmen.

H. L. Winter has resigned as sales manager of the Federal Motor Truck Co. of Detroit. He will take up similar duties with the Universal Motor Truck Co., of the same city.

R. M. Jones, sales manager for the Church-Field Motor Co., of Sibley, Mich., makers of Church-Field electrics, has resigned that post. His successor has not yet been appointed.

Walter C. Barnes, who for the past year has been connected with the advertising agency of Lord & Thomas, of Chicago, Ill., has been appointed advertising and publicity manager for the Moon Motor Car Co., of St. Louis, Mo.

Mason Towle, who has been in charge of the affairs of the Steinhart & Jensen Automobile Co., of Joliet, Ill., has accepted a position as manager of the Cadillac agency for Southern Ohio and Kentucky. His headquarters will be in Cincinnati.

Harry Fosdick, sales manager for the Stevens-Duryea Co., of Chicopee Falls, Mass., and one of the veterans of the industry, has resigned that office. His future plans are not public property, but it is known that he will locate in Detroit, where he will have to do with a popular priced car.

E. E. Guthrie, H. E. Westerdale and A. B. Caldwell have been appointed managers of the R. C. H. Corporation's branches in Kansas City, Chicago and Cleveland, respectively. R. C. Jordan, who formerly was connected with the Boston branch, has been transferred to the Los Angeles branch, where he will assume the duties of territorial manager.

Following the sale of the Mercer branch in Philadelphia to the Whiting Motor Co., W. A. Smith, advertising manager of the Mercer Automobile Co., who served also as manager of the Philadelphia branch, has been transferred to the factory in Trenton, N. J., where he will devote himself wholly to the advertising and publicity interests of the Mercer company.

W. J. Voit, manager of the Diamond Rubber Co.'s Spokane branch, has been promoted to the management of the Los Angeles establishment, which is now one of the largest Diamond branches in the West. He succeeds F. O. Nelson, who resigned after eleven years of service to engage in business for himself. The vacancy in Spokane has been filled by the promotion of J. O. Stewart, former manager of the Diamond branch in Oakland, who in turn has been succeeded by A. G. Potter, previously connected with the Diamond company's San Francisco office.

Henderson Staff Goes Over to Cole.

Having been formally absorbed by the Cole Motor Car Co., of Indianapolis, practically all of the men comprising the staff of the Henderson Motor Sales Co., which previously marketed the Cole output, have been taken in the Cole organization. Charles P. Henderson, head of the Henderson company, has become general sales manager for the Cole company, while H. C. Lathrop, who was secretary and treasurer of the sales company, has been appointed manager of the Cole branch in Indianapolis and allotted a generous slice of territory. Of the other former Henderson men, Edward Harris has been promoted to the position of assistant sales manager of the Cole company, while John Murphy, Henderson cashier, has been appointed secretary of the Cole concern. Homer McKee remains advertising director and H. C. Bradfield, traveling newspaper representative. Among the new men added to the post are Jay D. Riker, formerly with the Parry Mfg. Co., who has taken charge of the Cole promotion department, and Harlow Hyde, who has entered the company's advertising department.

Klaxon Baby is Christened "Klaxet."

The "baby" of the Klaxon line of electric signal horns has been christened the "Klaxet," and H. I. Stengel, of Spring Lake, N. J., who, among some 10,000 contestants, suggested the monicker, has been awarded the $100 prize which the Lovell-McConnell Mfg. Co., of Newark, N. J., offered for the most appropriate name submitted and accepted. Several others suggested the same name, but Stengel's was received first. The new horn operates on exactly the same principle as the Klaxon and the Klaxonet, its mechanism consisting of a steel diaphragm vibrated by a motor-driven steel ratchet wheel, and will be marketed under the same guarantee. It is a smaller horn than either of the other two, however, and will list at $12. It will be ready for the market about August 15th.

Newtone to Offer a Horn at $10.

Interest has been added to the already tense situation existing in the electric horn trade by the announcement that the Automobile Supply Mfg. Co., of Brooklyn, N. Y., maker of the Newtone horn, is about to add a popular priced horn to its line. It will be styled the Newtone Superior, and will list at $10. It is a smaller reproduction of the regular Newtone, and measures 11 inches over-all, with a seven-inch bell.

NEW YORK, JULY 18, 1912

CONCERNING THE USE OF "SILENT" CHAINS.

There is little doubt but that the popularity of the "silent" chain as a means of driving camshafts and magneto shafts is increasing, for already several well-known manufacturers of poppet-valve engines have adopted it, not to mention the several makers of Knight engines, whose products scarcely would be considered complete without it. Also, there is little doubt but that the use of the chain itself for this purpose is an excellent thing—provided the application is proper, and what is directly to the point, is in accordance with the experience of the chain makers themselves.

For instance, there is the question whether or not means of adjustment should be provided. From first examination, it would seem that there is little excuse for adopting a construction in which no means of adjustment is provided. It has been demonstrated that it is impossible to manufacture a chain to an absolute tolerance. That is to say, the limit of accuracy is governed by machine shop practice, and it is practically impossible to finish parts to closer than one thousandth part of an inch. As each chain is composed of a great number of individual parts the total error amounts to approximately the same number of thousandths of an inch as there are links in the chain, though it is not the same in every case.

This error causes a certain amount of slack on the non-driving side, of course, and it is this slack which causes whipping and imposes very much greater strains on the chain than it would be called upon to withstand under normal straight driving conditions. It must be understood that the load thrown suddenly on a slack chain causes stresses so severe that the normal stress appears small in comparison. As to just what the allowable slackness may be, authorities differ, though Hans Renold, of the noted firm of foreign chain manufacturers, has laid down an immutable law for his own factories which limits the maximum amount of slack in any high speed chain to 0.125 inch. The necessity of maintaining the minimum amount of slack consistent with proper operation is important enough in his opinion to warrant the extra expense involved in providing some means of adjustment.

Incidentally, by providing means of adjustment, the manufacturer eliminates any initial slack necessitated by the great difficulty of manufacturing a chain which shall join up and leave the exact amount of looseness that is desirable. As idler wheels impose additional wear on the chain, even if they bear on the reverse side of it, the problem resolves itself into the adoption of some form of driving or driven sprocket wheel that may be shifted to take up the slack, and though this method entails a certain amount of extra manufacturing cost, it may, in the opinion of not a few, be the means of distinguishing a really good car from a "pretty good" one.

CALIFORNIA'S DISPOSITION TO SECEDE.

Because the American Automobile Association has disciplined a race promoter and two officials who flagrantly violated its rules and its instructions and who permitted the public to be hoaxed by permitting the same cars to compete under different names, at least a small number of Californians have aroused themselves to a state of mind. They freely talk of seceding from the A. A. A. and setting up their own establishment and governing themselves. A San Francisco paper goes so far as to predict that if the A. A. A. "continues to rule on the lines of 'that it is It,' there is no question but what the Pacific Coast will break away from its authority and organize an association of its own;" all of which is interesting, if not convincing. But before California or any other part of the Pacific Coast decides to "break away," it best had commune calmly and seriously with itself. For that the A. A. A. is "it" and will continue to be "it," there is no shadow of a doubt.

It is the inherent privilege of any man or collection of men to "break away" and do what they will, but such performances are more or less amusing and usually terminate sadly. There is nothing to prevent seceders from playing in their own backyards, if they are content to do so, but if in California, or in any other part of the Pacific Coast, there are strong men and reasoning men who know the narrowness and folly of such backyard frolics, they will put an end to the secession talk as quickly as they know how. National authority is necessary to keep sport wholesome, and, lax in some things, the A. A. A., in the instance in dispute, acted the part it was organized to act and for the best interests of the sport. It is remarkable that in the State of California there can be found anyone ready to come out into the open and defend men who have been guilty not only of violating established rules and defying recognized authority, but who are party to an ill-smelling attempt to deceive the public.

On previous occasions and in other sports California has shown a disposition to flock by itself, but always the result has been to confine Californians to California. Outside their own State they were persona non grata and therefore without standing, which surely is not a condition to be deliberately courted.

PATENTS MAY OFFEND SHERMAN LAW

Massachusetts Court Expresses Belief that they May be Employed to Promote Monopolies—Case that Inspired Opinion.

Whether a patent may be so worked or otherwise employed as to constitute restraint of trade, and thereby violate the Sherman anti-trust law, is a point which was seriously considered by the Supreme Court of Massachusetts in the case of United States Shoe Machinery Co. vs. La Chappelle, the text of which just has been published; and while admitting that the final decision rests with the Supreme Court of the United States, the full bench of the Massachusetts Court expresses the belief that there is nothing in the Sherman act which reveals an attempt to exempt owners of patents from its sweeping provisions against monopolistic combinations.

In the La Chappelle case, the suit was based upon the specific performance of a contract between the parties, the agreement providing, among other things, for an employment by the plaintiff of the defendant in designing and improving shoe machinery, terminable at the will of either party, with stated wages. One paragraph of the contract bound the defendant to assign to the plaintiff any and all inventions, improvements and patents which he should make during the continuance of the contract and for ten years thereafter, and for a like period not to engage in any similar business. Since leaving the company's employment, the defendant has taken out a patent for an improvement in shoe machinery which he refuses to assign to the plaintiff, and the suit was brought to compel such assignment.

The main inquiry was, first, whether the plaintiff has acquired an illegal combination in restraint of trade, and, second, whether the contract sought to be enforced is a contract in direct aid of such monopoly. Both these subsidiary questions must be governed by decisions of the Supreme Court of the United States for they relate to interstate commerce and the meaning of the federal statute touching that subject. The defendant averred that in 1899 the plaintiff was constituted by the combination of seven or more pre-existing corporations competing with each other in two-thirds the States of the Union, being all the principal shoe machinery manufacturers in the country, and that by their merger the plaintiff acquired monopolistic control of the business of manufacturing, leasing and selling throughout the country machinery for the manufacture of footwear; that since 1899 it has bought competing corporations to the number of at least thirty for the purpose of diminishing competition, and thus gained control of 90 per cent. of the shoe machinery business; that it has achieved and maintained its monopoly of manufacture and trade and commerce by contracting with 95 per cent. of the inventors of shoe machinery for the entire product of their inventive skill through contracts similar in form to that with the defendant; and that by these means it has stifled competition, so that it now controls from 90 to 95 per cent. of all the shoe machinery in the country. The lower court excluded all evidence under this averment.

The court points out that in a wide sense the term monopoly defines a combination or an organization so extensive, exclusive and unified that its tendency is to prevent competition in its comprehensive sense, with the consequent power to control prices to the public harm. The plaintiff was decided to approach closely to this definition, and the further question then arose whether a combination of several patentees of competing devices is within the inhibition of the antitrust statute. The holder of a patent is given an absolute monopoly of the invention covered thereby, not affected in any degree by the Sherman act. A combination of persons who had been competing in the market under sundry patents, for the purpose of ending the competition and acquiring thereby complete mastery of a branch of interstate commerce, was the gravamen of the defence. The decision emphasizes the point that nothing in the Sherman act reveals an intent to exempt the owners of patents from its sweeping provisions against monopolistic combination, and states that there appears to be no inherent natural distinction between owners of patents and owners of oil which would justify the application of the statute to one and not to the other.

With respect to the final contention that the contract is in direct aid of the illegal combination amounting to monopoly of trade in contravention of the federal statute, the court cites numerous cases which have been heard by the Supreme Court of the United States, and draws the distinction that such contracts, to fall within the intent of the Sherman act, must exert a direct restraint upon commerce. The conclusion is that patent agreements of the kind in question, which was one of many similar contracts with individuals enough to constitute a practical monopoly of skill in that department, are by virtue of their common association and interest, a part of an illegal combination. The term of the contract provision with the defendant requiring assignment of inventions for ten years after the termination of employment savored of restraint of trade, and while a single such contract is far away from interstate commerce, the individual aspect is lost in the larger relations of the case. The exceptions of the defendant are sustained by the court on the ground that, as an integral part of an unlawful scheme for monopolizing commerce between the State which cannot be perpetuated successfully without contracts of like tenor with all practising a like craft, the agreement in questions partakes of the illegality of the scheme as a whole.

July 9-24, Indianapolis, Ind. — Annual Four States tour of the Indiana Automobile Manufacturers' Association.

July 15-20, Milwaukee, Wis.—Reliability tour, under the auspices of the Wisconsin State Automobile Association.

July 21, St. Louis, Mo.—Track races under the auspices of the Universal Exposition Co.

July 22-28, Dallas, Texas—Farm and Ranch Tour under the auspices of the Dallas Automobile Club.

July 24, Scranton, Pa.—Track races under the auspices of E. A. Cusick.

July 24-31, Minneapolis, Minn.—Reliability tour of the Minnesota State Automobile Association.

July 27, Wilkesbarre, Pa.—Track races under the auspices of E. A. Cusick.

July 27, Grand Rapids, Mich. — Track races promoted by the Grand Rapids Automobile Club.

August 8-10, Galveston, Tex.—Beach races under the auspices of the Galveston Automobile Club.

August 24, Uniontown, Pa. — Hill climb under the auspices of the Automobile Club of Fayette County.

September 2-3, Indianapolis, Ind.—Races on the Motor Speedway, promoted by the Indianapolis Motor Speedway Co.

September 7, Hadine, Minn.—Track races promoted by the Minnesota State Fair Association.

September 17, Milwaukee, Wis.—Grand Prize road race under the auspices of the Milwaukee Automobile Dealers' Association.

One Ticket for Both New York Shows.

It has been definitely settled that one admission fee will admit to the shows in both Madison Square Garden and Grand Central Palace, New York City, next January. It was anticipated that such a provision would be made, but it was not formally decided until Thursday last, 11th inst., when the Automobile Board of Trade held its regular quarterly meeting in New York City, the exhibitions in both places constituting one show, under the auspices of that organization. Pleasure cars will be housed in both buildings during the week January 11-13. They will be replaced the following week, January 20-25, by commercial vehicles. At last Thursday's meeting of the Board of Trade, resolutions appropriate to the death of Alfred M. Mayo, treasurer of the Knox Automobile Co., which is one of the oldest members of the Board of Trade, were spread on the minutes.

ELGIN ROAD RACES ARE RESCUED

After One Chicago Club Drops Them, Another Unexpectedly Steps in—The Program as Rearranged.

At the eleventh hour the Elgin road races, which, as stated in the Motor World last week, were abandoned by the Chicago Motor Club, were rescued, and from an unexpected quarter. For the Chicago Automobile Club, which has not promoted a speed event since the Crown Point road races of 1909, has stepped into the breach and will run the Elgin races in conjunction with the Elgin Automobile Road Race Association, and it is confidently expected that sufficient entries will be signed up to make the affair a success.

The race, which had been sanctioned to be run on August 23rd and 24th, has been postponed one week, so as to give the new management sufficient time to get in "apple pie order," and will be run on Friday, August 30th, and Saturday, August 31st, provided sanction is granted by the contest board of the A. A. A., and of this there seems to be no doubt. Unlike the procedure which heretofore has been adhered to, of running three preliminary events on the first day and the free-for-all on the second, this year two events will be run on each day and all will be for non-stock cars.

On Friday the program will comprise a Class C event for cars with displacement of 231-300 inches, which will go for 152.5 miles or 18 times around the course, and a Class C event for cars with displacements of 301-450 inches, which will go 24 laps, or a little better than 203¼ miles. The prizes for the first event will be the Aurora trophy and $700 in cash for first, $200 for second and $100 for third. For the second event the prizes offered are the Illinois trophy and similar cash prizes.

On Saturday, however, will be witnessed the "big" races, the first a 254-mile event, which will be run for the Elgin National Trophy and which is open to Class C and Class E cars with displacements up to 600 inches. Besides possesion of the Elgin trophy for a year, the winner of this 30-lap race will receive $1,000 in cash, second will receive $300 and third $200.

The free-for-all event, which in all likelihood will be the more interesting of the two which are on the program for the second day, will go for a little better than 306 miles, or 36 circuits of the course, which surveys 8 miles 2,499 feet. This event is open to any car which conforms to the definition of a motor car as laid down by the rules of the A. A. A. and is worth $1,750 to the winner, while second and third will receive $500 and $250, respectively.

Whether "cut price" entry fees which have been inaugurated—the fee being $100 a car as against $300 which was charged last year—and an increase in the value of the cash prizes, which is more than double the value of the prizes heretofore offered, will draw sufficient entries to make the races a success cannot as yet be foretold.

Pabst Trophy to be Milwaukee-made.

When Col. August Pabst, of Milwaukee, Wis., decided to offer a trophy for a light car race to be run near that city in September in connection with the Vanderbilt Cup and Grand Prize contests, that he planned no unworthy gift is indicated by the size and detail of the object designed by the Louis Esser Co., of Milwaukee, whose suggestion, shown by the accompanying illustration, was chosen from a field of 22. When completed the silver cup will be over three feet high and sixteen inches in diameter. Surmounting it will be a figure of Mercury, the messenger of the gods of ancient Greece, his foot upon a domed base encircled by cantas leaves, this much forming the cover, which will be removable. Upon a shield on one side of the cup proper, in a Louis XIV design, will be a speeding automobile. Winged automobile wheels ornament the legs and the whole rests upon a mahogany base.

PABST SILVER TROPHY

Lack of Entries Kills Two Events.

Forestville, N. Y., which was to have witnessed a hill climb on Sunday afternoon last, July 14th, was disappointed. The program was abandoned by the Forestville Motor Club only after several weeks of "rooting" for entries had been carried on to no avail. A reliability run, which was to have started from Cleveland, Ohio, under the auspices of the "Cleveland News" on Monday, July 15, also did not materialize.

FUN MARKS FOUR STATES TOUR

Indiana "Boosters" on Sixteen Days' Tour to Advertise Their State—Frolics and Factory Visits En Route.

Singing their "merry roundelay" to the accompaniment of a pipe organ which is mounted on a Nyberg truck and a player piano carried by a Whitesides, the only other commercial vehicle in the caravan, the Four States tourists who left Indianapolis on Tuesday last, 9th inst., on the annual "boost Indiana" trip, are flooding each of the towns along the 1,200 mile route with automobile literature, talk, and the strains of that hymn of good fellowship, "Hail, Hail, the Gang's All Here."

The "Howdy, folks, howdy!" slogan first was sounded at Peru, Ind., which was reached on the afternoon of the 9th, where a luncheon served at the expense of the Great Western Motor Co. and a trip made through the factory where the car chosen for pathfinder of the tour is made. At Kokomo, which was reached later in the afternoon, the Haynes factory was looked over, after which the party proceeded to Fort Wayne, the night control, which was entered by the Four Staters by at least as many different routes. The cause of the split was the absence of a confetti-marked trail, which ended abruptly at Huntington, where the supply of paper bits carried by the confetti car had given out. An abundance of confetti having been obtained by the course marker, the tour left Fort Wayne on the morning of the 10th, and it was not long before the cars were kicking up Ohio dust. Lima, the night control, was reached without incident, and the morning of the third day was spent in an inspection of the Gramm truck factory, and in listening to the exhortations of a "suffragette," who took up a collection for the "cause," but later was shown to be one of the tourists who had impersonated a female and hoaxed his fellow travelers.

The evening of the third day disclosed the "boosters" at Tiffin, while Akron was reached on the evening of Friday, 12th. Saturday was a "day of rest" and was spent in inspecting the manufacture of tires at the various factories in the tire city. Sunday morning was spent in a "plunge bath party" tendered by Firestone Esterly. The tourists will "do" West Virginia and Kentucky before they head about for the return to the Hoosier City, which, if things go according to schedule, will be reached on Wednesday next, July 24th.

Bathrick Heads Battle Creek Club.

George H. Bathrick has been chosen to head the newly formed Battle Creek (Mich.) Automobile Club. The other officers are: Vice-President, W. I. Fell; secretary-treasurer, H. W. Johnson; directors, N. E. Hubbard, C. Grandin.

TETZLAFF SHINES IN PORTLAND

Takes Five Out of Ten Events—Oldfield Heinemann and Fritsch also Figure in Oregon Meet.

Match races made up half of the program of the two days racemeet which was run on the Country Club mile track at Portland, Ore., July 9th and 10th, by the Portland Automobile Club, for of a total of ten events, five being of the match variety. Theodore Tetzlaff, who was present and who naturally piloted a Fiat machine, captured five of the ten events on the program.

On the first day of the meet William Fritsch (Cino) took a five mile match race from Lew Heinemann (Benz), completing the distance in 5:21½. Tetzlaff won the five mile Class E event from a field of three, his time being 4:59. Barney Oldfield, who piloted the Christie's front-drive car, made the best time in the single mile time trials, when he covered the distance in 53 seconds. Tetzlaff won the five mile match race from Fritsch in 4:47. The free-for-all event, which was to have gone for five miles, was called off when Chris Dundee, a local driver, who was at the wheel of a White steamer, met with an accident which wrecked the machine and nearly killed the driver.

A three-mile match race between Heinemann (Benz) and Fritsch (Cino), which was run on the second day, resulted in a victory for the former, who covered the distance in 3:01. Oldfield "tackled' 'the winner in a two-mile match event and drove the Christie over the tape four seconds ahead of the Benz, the time being 1:51. Tetzlaff compelted the first of the five-mile Class E events in 5:16⅗, winning from Verbeck (Fiat) and Hill (Fiat), and the second in 4:39⅕, winning from Fritsch (Cino) and Heinemann (Benz), who finished in the order named. Heinemann took a mile match race from Fritsch in 54⅗ seconds. A single mile time trial which Tetzlaff completed in 53⅕ seconds marked the end of the second day's program. The summary:

Tuesday, July 9th.

Five miles, match race—Won by William Fritsch (Cino); second, Lew Heinemann (Benz). Time, 5:21½.

Five miles, for cars with displacements of under 600 inches—Won by Theodore Tetzlaff (Fiat); second, Verbeck (Fiat); third, Hill (Fiat). Time, 4:59.

One mile, time trials—Barney Oldfield (Christie), time, :53; Tetzlaff (Fiat), time, :54; Dundee (White Steamer), time, :54⅗.

Five miles, match race—Won by Theodore Tetzlaff (Fiat); second, William Fritsch (Cino). Time, 4:47.

Wednesday, July 10th.

Three miles, match race—Won by Lew Heinemann (Benz); second, William Fritsch (Cino). Time, 3:01.

Two miles, match race—Won by Barney Oldfield (Christie); second, Lew Heinemann (Benz). Time, 1:51.

One mile, time trial—Theodore Tetzlaff (Fiat). Time, :53⅕.

Five miles, for cars with displacements of under 600 inches—Won by Theodore Tetzlaff (Fiat); second, Verbeck (Fiat); third, Hill (Fiat). Time, 5:16⅗.

Five miles, for cars with displacements of under 600 inches—Won by Theodore Tetzlaff (Fiat); second, William Fritsch (Cino); third, Lew Heinemann (Benz). Time, 4:39⅕.

One mile, match race—Won by Lew Heinemann (Benz); second, William Fritsch (Cino). Time, :54⅗.

Police Stop Moross's Sunday Meet.

As a sequel to the "cold shoulder" which was directed toward E. A. Moross and his more or less merry men when they made their appearance at Davenport, Ia., on the 4th inst., the sheriff of Canton, Ohio, placed two of the headliners of the troupe, "Bob" Burman and Harry Kyle, under arrest on Sunday last, 14th inst., for breaking the blue laws, by participating in a racemeet on the Sabbath. The pair was placed under arrest on a warrant sworn out by the members of the Christian Endeavor Society after Burman had succeeded in breaking the local track record for one mile in the first and last event which was run, driving the Blitzen Benz twice around the half-mile circuit in 1:12½. Bail was quickly furnished by the manager, but to the great disappointment of the crowd the races were postponed until the following day. So great a disturbance was raised by the 10,000 spectators that it took a detachment of the Ohio National Guard to prevent more serious trouble.

Even the threatening weather which greeted the racers when they turned out on the track on the following day, Monday, 15th inst., was not considered sufficient excuse to again disappoint the crowd. Four events were run, and but one, 25 miles, for cars with displacements under 451 inches, was shortened on account of the threatening rain, 10 miles only being run. The summary:

Ten miles, for cars with displacements of under 451 inches—Won by Robert Burman (Benz); second, Kyle (Cutting). Time, 13:27½.

One mile, time trial—Robert Burman (Benz). Time, 1:10.

Three miles, for the Remy Brassard and trophy, first heat—Won by Robert Burman (Benz); second, E. A. McDonald(Benz); third, Kyle (Cutting). Time, 2:35. Second heat—Won by Robert Burman (Benz); second, E. A. McDonald (Benz); third, Kyle (Cutting). Time, 2:40.

Three miles, free-for-all handicap—Won by E. A. McDonald (Benz); second, C. J. White (Velie); third, Kyle (Cutting). Time, 3:01.

FOURTEEN IN WISCONSIN CONTEST

Less Rigorous Rules Than Formerly Promise More Clean Scores—Five Days of Travel Entailed.

Fourteen motor cars, groomed for a tussle with the sandy and otherwise bad roads of Wisconsin, left Milwaukee on Monday morning last, 15th inst., in the Wisconsin State Automobile Association's third annual reliability tour for the Sentinal Cup. The first day's journey led to Beloit, a distance of 113 miles, where the tourists were banqueted by the Warner Instrument Co.

Although the 610 miles of state highways which will be traversed by the caravan before the return to Milwaukee on the evening of Friday next, July 19th, are, owing to the late spring, which has handicapped road work, by no means in the best of condition, it is confidently expected that clean slates will be the order, since the rules under which the tour is being conducted are less stringent than those that obtained in previous years. Grade III rules are in force, under which penalties are awarded only for work done on the car while "en route"; the technical examination of the cars at the conclusion of the contest is done away with. Unlike the previous contests, fuel need not necessarily be taken on only at the noon or night control, for no penalty attaches to the filling of tanks on the road.

The itinerary of the tour is as follows: July 15, Milwaukee to Beloit, 122.9 miles; July 16, Beloit to Baraboo, 133.2 miles; July 17, Baraboo to Oshkosh, 134.5 miles; July 18, Oshkosh to Green Bay, 109.3 miles; July 19, Green Bay to Milwaukee, 129.1 miles.

The contenders are: Emile Hokanson, Buick; Jacob Hanson, Case; P. B. Hustis, King; James Holmes, Krit; Jay E. Morehouse, Hupmobile; W. H. Diener, Ford; Thomas R. Bell, Flanders; W. H. Soules, Flanders; Charles F. Spooner, Oakland; R. D. Rockstead, Paige; H. R. Gallun, Marion; R. G. Bates, White; H. O. Stenzel, White; J. D. Babcock, Franklin.

Thompson Enters Motordrome Project.

Replacing H. E. Hoyt, who is an official of the American Potash Co., Jefferson DeMont Thompson, a far more experienced man, has been elected president of the Metropolitan Motor Speedway Association, which is undertaking to build the two-mile motordrome on the New Jersey meadows near Newark. Although of late he has played no part in automobile affairs, Thompson at one time was a national figure. For several years he was chairman of the A. A. A. racing board, and during the three years, 1906-08, he was chairman of the Vanderbilt Cup Commission. He was also treasurer of the Long Island Motor Parkway. Thompson is a man of means who has traveled extensively.

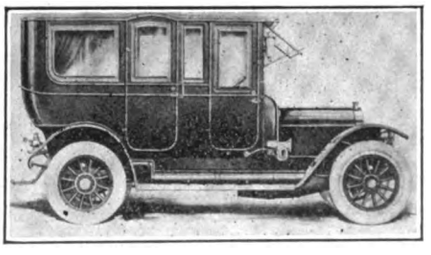
KNOX'S "LITTLE SIX" LOOMS LARGE

Newcomer Proves an Uncommonly Attractive Creation—Its Features and Refinements that Mark Other Knox Models.



When a veteran like the Knox Automobile Co., of Springfield, Mass., essays the production of a new model it is a practical assurance of its complete and unqualified success. If there was one word which combined in its meaning such qualities as beauty, a smoothness of action which surpasses even that of the other cars upon which the Knox reputation has been built, flexibility and, last but not least, dependability, then that word best would describe the new Knox "little six," which has been more than two years coming through the mill and which at last has reached its finished form. It has 12 years of experience builded into it and it looks and acts the part. It is the "baby" of the line in the sense that it just has been born, so to speak, and though it is smaller and lighter than the standard six-cyinder Knox car, it is not by any means the smallest car in the line.

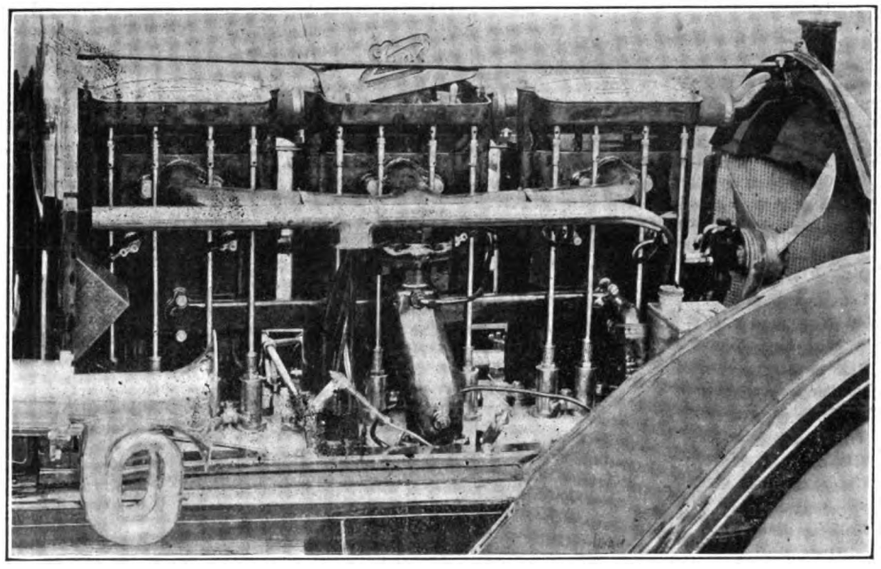
There are two four-cylinder models included, both of which are rated at 40 horsepower, the bore and stroke being in each case 5 x 5½ inches, the bix "six," rated at 60 horsepower, in which the bore and stroke is the same as in the fours, and the new "little six," which is rated at 46 horsepower and which has a bore and stroke of 4⅜ and 5½ inches, respectively. Because the older cars in the line have suffered so little alteration as to be scarcely noticeable, it may be taken for granted that no room for improvement could be found in them. Improvements have been made, as a matter of course, and minor refinements, but in the main they are the same Knox creations that have rolled over the roads for several seasons past. It is but natural, therefore, that chief interest should attach to the new model, because it is new and also because it incorporates a number of features never before found in Knox cars.

In bringing out the new "six," it is explained by H. G. Farr, who for practically the whole life of the company has been its chief engineer, it has been sought to develop a "balanced" motor and chassis that would permit continuous touring over all kinds of roads, good, bad and indifferent, without the necessity for frequent gear shifting. Though an exceptionally speedy creation was not sought, it is modestly admitted that with the car in touring trim 73 miles an hour has been attained. The search was rather for high torque at low engine speeds—obviously, continuity of torque has been obtained by using six cylinders—which is the only feature that will permit of long, hard pulls through deep sand or up steep hills on "high." Cognizance has been taken of the fact that not every one likes to "rush" hills, and that even when they do it is not always perfectly safe to do so. The alternative, of course, is to use a lower gear, though the necessity for this expedient has been removed in the new Knox "little six" as much as it is possible ever to eliminate it.

TWO VIEWS OF THE NEW KNOX "LITTLE SIX" SHOWING V-TYPE RADIATOR

KNOX 7-PASSENGER BERLINE

In the course of an afternoon's demonstration of the ability of the car, a portion of one of the worst hills in the vicinity of Springfield—the gradient is said to be well over 20 per cent.—was negotiated on high gear without the slightest difficulty and at moderate speed. There was no necessity to rush at the hill, and, what is perhaps more to the point, there was absolutely no laboring of the engine. Even when the engine was all but stalled on one exceptionally steep spot, which would cause many another engine to complain even if the intermediate gear were used, the slight pound which generally is apparent, and which legitimately may be looked for, was conspicuous by its absence. The first sensation almost was one of disappointment becaues the engine buckled down to its work without a sign of the tremendous strain upon it, but it quickly changed to one of admiration for the pulling power and the quietness of the power plant.



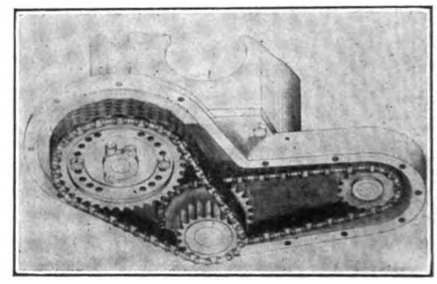
It was the same way on the straight level stretches that lie just outside the city. There was the sense of exhilaration that is given by almost any six-cylinder motor coupled with an acceleration and pulling power at low speeds that was nothing short of astonishing. Time and again the uncomplaining motor was throttled down until the car crept along at snail's pace—on high gear, of course—and it was easy to count every explosion, or, rather, to count the firing of the cylinders by the sound of the magneto contact breaker. In fact, there was little else to indicate that the motor was running, and another unusual feature was that it was virtually as quiet at 60 miles an hour as it was at 20 miles an hour.

In explanation of the great pulling power at low speeds and the rapid acceleration, it is merely necessary to examine the dimensions of the bore and stroke, which are 4⅜ x 5½ inches. Here, though the long-stroke principle has been adhered to, there has been no attempt to carry the ratio of stroke to bore to the extreme, as has been done in so many other cases with results which, in the minds of not a few, are doubtful. Instead, the ratio has been maintained on the conservative side, and the wisdom of the designers amply is reflected in the performance of the car. Of course, efficiency of carburation and scavenging of the burned gases has no little to do with the problem and this, too, has been attacked in a manner that suggests the care in designing that everywhere else is apparent. The intake

Digitized by Google

manifold is short, as may be seen in the accompanying picture, and it is completely water jacketed. The gas, therefore, is warmed before it enters the cylinders and becomes to all intents and purposes a perfectly homogeneous mixture which burns completely and quickly. The completeness of combustion is indicated by a total absence of smoke or obnoxious odors at the exhaust pipe.

The location of the two manifolds, by the way, is quite different in the new model. Instead of being both on the same side, they are separated and are on either side, the change being made to permit the option of either right or left hand position of the steering wheel. The emergency brake and gear shift levers are located in the center of the footboard in any case. Another noteworthy difference between the new-

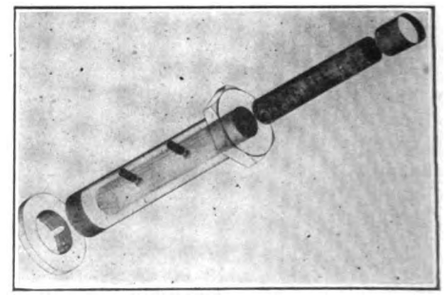


KNOX "LITTLE SIX" ENGINE SHOWING NEW VALVE COVERS

comer and the older "six," and one which in no small way effects quietness of operation, is that the overhead valve mechanism is completely enclosed by means of light, removable aluminum casings; they are shown quite clearly in the accompanying picture.

This feature is merely by way of quieting such slight valve noises as are necessary and cannot be eliminated by the most careful designing. In the method of driving the cam shaft and magneto shaft, however, a preventive of noise rather than a cure is employed and is in the form of a "silent" chain. In this connection it is interesting to note that in choosing the size of the chain to use, the designers were not content to abide by the recommendations of the chain manufacturer, but conducted their own experiments to discover the best size to use under all conditions. The result was that a chain of 50 per cent. greater load capacity than that recommended by the manufacturer finally was adopted. Indicating the forethought of the designers in this respect, after an exhaustive test during which the car was driven some 10,000 miles, the "stretch" in the chains was so small as to be negligible. Despite this fact, however, provision for taking up such slack as may result from wear is made, the Vernier adjustment showing in the picture.

Part of the standard equipment on both the six-cylinder models is an Esterline dynamo electric lighting system. On the new "six" the dynamo is driven from a continuation of the magneto drive shaft, leather universal joints being interposed between both the magneto drive and the dynamo drive. The magneto is the latest Bosch instrument and forms part of the Bosch ZR6 system. The principle feature of the magneto is that it is completely waterproof and therefore impervious to the unwelcome attentions of careless washers and to the elements. Cooling is effected by a positively driven centrifugal pump and a liberal sized radiator, the most noteworthy feature of which is that it is of the V-type, which bids fair to appreciate materially in popularity in the near future. Outside of reasons of a strictly esthetic nature, the new style radiator has been adopted because it permits slightly greater cooling surface and its shape is such that the suction through it is uniform over practically its entire surface. The lubrication of the engine is the same as that which has been used with conspicuous success in all Knox engines for a number of years. Under the system, the oil is forced under pressure to all the main and auxiliary bearings and is maintained in constant circulation by means of a pump located outside the crankcase, where it is instantly accessible.



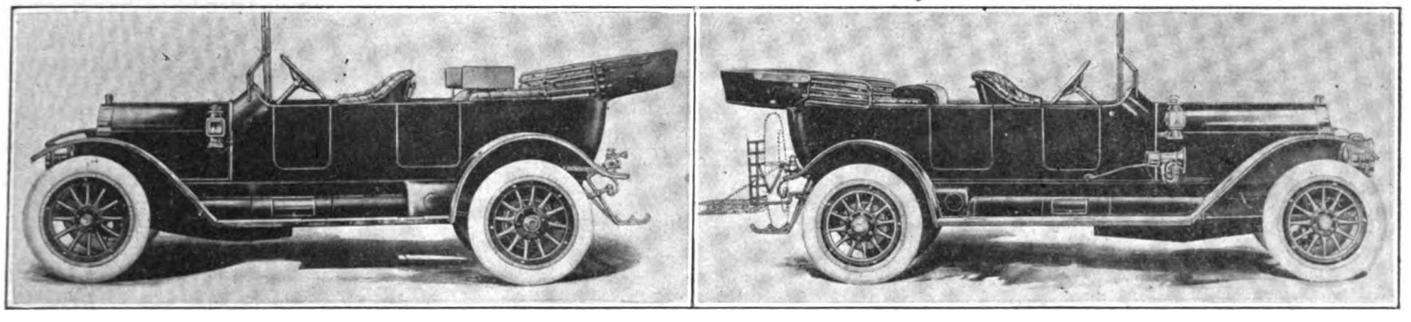
The remainder of the chassis differs little from standard Knox practice, except for a number of refinements and minor alterations, which, though small, nevertheless have definite bearing on the car as a whole. Thus, for instance, though the change gear mechanism is of the same three-speed selectively operated type that has been used for years, and now is used in all the Knox cars, a slight variation has been made in the length of the lay shaft in order that the speedometer may be driven from it. This position of the star wheel, it is explained, permits more accurate driving of the instrument for the reason that no amount of wheel bouncing can effect the reading or cause the dial hand to oscillate. Incidentally, the ordinarily rapidly rotating gears are fully protected from the influence of road dust and dirt, and therefore run for

CAMSHAFT CHAIN DRIVE

practically indefinite periods without wear and without attention.

Another slight difference lies in the method of spring bolt lubrication. The bolts themselves, as may be seen by the picture, are unusually large and provide the maximum of bearing survice. By way of reducing wear and consequent rattles, the bolts are drilled out for two-thirds of their length, with smaller holes leading to the bearing surface. The small holes are plugged with felt and a roll of the same material thoroughly soaked in heavy oil is inserted in the large drilled passage. A

SPRING BOLT CONSTRUCTION



movable plug at the end serves to maintain the felt in position and also to force the lubricant to the bearing surface.

Power is transmitted to the change gear mechanism through the intermediary of the well-known Knox three-plate clutch, the smooth action of which is ensured by cork inserts. The drive is by propeller shaft in a practically straight line to a new form of full-floating rear axle, which differs in several respects from the axles which have been used in Knox cars in the past. In the first place, the axle is of Knox design and construction and in appearance suggests light weight combined with a ruggedness that is unmistakable. One of the particular features of the design is that all load is carried on annual ball bearings, which are

Digitized by Google

backed up with thrust bearings. It is to this construction that the designers lay the axle's smooth action and freedom from all noise. To the unpracticed ear, it would be difficult to determine at 50 miles an hour whether the driving gears are of the orthodox bevel type, which they are, or whether a worm drive is used, so silent is the construction.

The spring suspension is the same in the new model as in the older ones and remains unchanged, the leaves of the upper portion of the rear three-quarter elliptic members being extended slightly to act as buffers against rubber pads placed on the axles. The front springs are of the semi-elliptic variety and, like the rear springs, are of the proper length to provide the requisite resilience without undue rebound; Truffault-Hartford shock absorbers are regularly fitted both front and rear. The wheelbase of the new car is 130 inches and the wheels are shod with Fisk demountable rims and 37 x 5 tires all around.

TWO KNOX TORPEDO MODELS—4-CYLINDER 45 HORSEPOWER AND 6-CYLINDER 60 HORSEPOWER

The new car lists at $4,350 with any style of open body, $100 and $150 being added for limousine and landaulet types, respectively. The equipment which is included for the price is unusually complete and numbers such items as top, windshield, speedometer, electric light system complete with all the necessary lamps, power driven power pump, acetylene engine starter, gasolene tank gauge, tire carriers and trunk rack, tools, jack, repair parts, etc.

The older cars in the Knox line remain substantially the same, as already has been told, and include the models 45 and 46, both of which have four-cylinder motors rated at 40 horsepower and having cylinders which measure 5 x 5½ inches. The six-cylinder 60-horsepower model has the same bore and stroke and, like the others, is furnished in a variety of body styles, ranging from a two-passenger "raceabout" to a seven-passenger Berline limousine. On any or all the models, the option of either nickel or brass finished trimmings is given, and the list of stock colors in which the cars are finished is of such variety as to leave little to be desired. The distinctive body designs which have been a striking characteristic of Knox cars during the past season are continued with several detail improvements that tend toward greater harmony of outline.

STEARNS STAFF "SEES THINGS"

Visits Factory for Annual Conference, when New Models and New Plans Are Disclosed—Record Orders Booked.

Marking the first anniversary of the birth of the Stearns-Knight car, the F. B. Stearns Co., of Cleveland, O., having elected just one year ago to equip all its cars with the Knight engine to the complete exclusion of all other types, the annual convention of its distributors and sales managers, which took place last week, was the largest ever held in the experience of the company, and among other things served to bring to light several new features which have been adopted for the new series of cars which soon will be ready for the market. So convincing were the models disclosed that the number of contracts closed for immediate delivery totaled the largest single week's business ever done by the company.

Though the cars will be continued in practically the same form as has enabled the Stearns company to double its business since its adoption of the Knight engine, a number of slight, though nevertheless important, changes have been made. Thus, for instance, the finish hereafter will be in nickel plate and black enamel instead of in brass. Another change which was disclosed was that the already complete equipment of the cars has been made still more complete by the addition of a self-cranking device. The remainder of the equipment remains the same and includes top, windshield, speedometer, dynamo, electric lighting system, electric horn, demountable rims, etc. The position of the tire carriers also has been altered; they now are located at the back of the tonneau, the clearing of the running boards being completed by the relegation of the tool boxes to less conspicuous positions beneath the seats.

The convention was opened by President Frank B. Stearns, who made a short address that was followed by others from Secretary McEwan, T. A. Boyle and H. H. Hower. On Tuesday night, 9th inst., the visitors and heads of departments of the home office were entertained at a banquet given by President Stearns at the Cleveland Automobile Country Club, at which the future plans of the company and many of the phases of the business peculiar to the marketing of Knight-engined cars were discussed at length.

Rambler Increases Disclosed at Conference.

At the annual convention of salesmen of the Thomas B. Jeffery Co., which occurred last week at the Kenosha, Wis., factory of the company, the most important piece of news that was imparted to the 75 men who had gathered from all parts was that the factory output next year will be increased by 60 per cent. In the report, which dealt with the subject, it was brought out that the increase in the sales of the Cross Country model, the Rambler leader, amounted to 126 per cent. more than the sales that were made for the corresponding period the year before. The actual number of cars shipped from the factory showed an increase of 20 per cent. over the best previous year. Incidentally, Rambler dealers have increased more than 100 per cent. during the past year.

Australia Increases Its Automobile Imports.

It is doubtful if there are many who appreciate the position that Australia occupies with regard to the automobile industry or the importance which attaches to that country's steadily increasing importation of automobiles and parts. For instance, in the year 1911 the eight states imported automobiles, including pleasure and commercial vehicles, and accessories, to the value of $6,185,090, of which the state of New South Wales, which took almost as much as the other seven states combined, took $2,645,120 worth, leaving $3,539,970 for the others. Naturally, the greater portion of the importation came from Great Britain, though America is next, and within the past year has displaced France for second. The value of cars imported from Great Britain was $2,738,930, as against $1,302,385 from the United States. As indicative of the strong demand for American-made cars and trucks, New South Wales alone took $641,970 worth of American products as against $1,163,500 worth of British products, both figures representing a substantial increase over those for the similar period last year.

WASTE POWER THAT IS PUT TO USE

Factory in Which Engine-Testing Operations Are Made to do Double Duty—How the Purpose is Attained.

There are few industries to-day to which the application of scientific management in some form or another is not possible; and where it is applied, the results almost invariably prove beyond cavil that in the conservation of energy with the least waste and the most direct application of efforts lies the real secret of success in almost any endeavor and certainly in every business. A clever instance of the forethought and attention to detail that lies back of the principle is to be found in the La Porte (Ind.) shops of the M. Rumely Co. whose farm implements and agricultural tractors are known wherever such things are used. It consists, briefly, in putting to useful purpose power which ordinarily and every day in hundreds of factories deliberately is thrown away.

It is needless to point out that every engine that is completed must undergo a certain "course of sprouts" and be run for a certain length of time on the testing stand. Under the usual order, the power that is developed during the time the test is in progress is considered valueless except to give readings and to "run in" the motor. It remained for the Rumely company, however, to put this power to other and more specific uses; it is employed to drive other machinery and to generate electric lighting current, and so successful has the experiment proved that savings represented by figures of four digits are effected. Incidentally, though but part of the available power is used at present, it is planned in the near future to increase the size and facilities of the testing house so that all the power utilized in the manufacturing plant can be drawn from engines that are undergoing tests.

The method of utilizing the power is plainly apparent from the accompanying illustration, which shows the company's present testing house and a number of its kerosene-burning agricultural tractors belt connected to dynamos undergoing tests. The test house, which is of steel and concrete construction, is 168 feet in length by 62 feet in width, and is fitted with a central platform on which are mounted eight 30-kilowatt generators which are belted to the motors of as many Rumely "Oil-Pull" tractors. The motor of each tractor is "run in" for at least 48 hours and the electric power generated is utilized and effects material savings in fuel bills. After the two days' run, the tractor is shifted to the other side of the platform and connected with a water brake for a final test and horsepower reading.

HOW THE RUMELY CO. HARNESSES THE POWER GENERATED AND USUALLY WASTED IN ENGINE TESTING

Vanderbilt Suit Involves Second Maker.

Although the denial by Judge Benedict in the Supreme Court for Kings county, N. Y., of a motion by the Pope-Hartford Auto Co. of New York City to retry the case brought against it by Thomas Muller, who was injured in the 1910 Vanderbilt Cup race, is a temporary setback for the defendant, the October term of the Appellate Division of the Second Department may be productive of results more favorable to the Pope-Hartford concern, for at that time two appeals will be argued, one from the order denying a retrial and the other from a verdict of $22,500 previously secured by Muller. Both probably will be heard together, as, while the motions are separate, they are alike in interest and affect a single legal action. The new evidence involves another car and maker.

Muller was struck by a car and was badly injured and brought suit against the Pope-Hartford company, claiming that its entry, driven by Jack Fleming, was the offending vehicle. The jury in the first trial agreed with Muller, but after the trial the Pope-Hartford company unearthed additional evidence supporting its claim that Muller was mistaken in his identification of the car which struck him and asked a retrial, supporting its motion with affidavits by Joe Dawson and his mechanician, who rode the Marmon entry, that the Marmon car struck a man at the point where Muller was injured. The Pope-Hartford car, the claim is, was drawn up at the roadside, some distance away, repairing a tire at the moment the accident occurred.

Seek to Escape "Gasolene Barons'" Grasp.

As a means of escaping the grasp of the men who control Great Britain's gasolene supply and to provide the fuel at reasonable rates, an effort is being made to form a co-operative "Petrol Supply Association" composed of car owners. The scheme embraces the formation of an organization with a capitalization of £25,000, the shares to be £1 each. The promoters of the association declare that the condition of the private owner is "absolutely helpless" and that co-operation offers the only avenue of relief. They believe it is possible to supply gasolene at a price not exceeding 24 cents per gallon, which price, they maintain, will, at the same time, give the members of the proposed association a fair return on their capital.

PARTS DRIVERS MAY PLAY IN INFLUENCING TRUCK SALES

Two Instances Drawn from Real Life Which Strikingly Illustrate Conditions That Are Encountered—The Employer, Willing to be Convinced and Yet Loyal to His Old Horse Drivers, Who Remained Unconvinced, and the Reasons Therefor.

The Designing Engineer was sitting on the small of his back with his feet on the desk, reading a somewhat lengthy letter that caused his face to assume an expression indicating feelings too deep for ordinary words, and ever and anon as he read he gave his head an impatient jerk to one side, as if to make special note of those parts of the communication that caused him the most annoyance. When he had read it through he turned back and started again, and it was at this juncture that his friend the Inquisitor, ignoring the diminutive office boy, shoved the door open and entered with his usual lack of anything in the nature of ceremony.

"Well, how's the D. E. and the theory of intermolecular animalcules?" he jollied. "What's the latest in—— Why, old top, what's up? Haven't you paid your bills?"

The D. E. glared at his visitor for a moment without speaking and then once more cast his eyes on the letter in his hand.

"That's what's up," he replied, sourly. "If you can be rational for a few minutes and stop making fool remarks you can read it and sit with me awhile and help me swear. My individual ability is unequal to the occasion."

The Inquisitor read the letter, and as he did so his face lost its ordinary expression of jollity, for the two were close friends, and anything that touched the D. E. touched the Inquisitor also. The letter was from a big contracting firm for which the D. E. had planned a somewhat extensive installation of motor trucks, and was to the effect that the work done by the single machine that had been installed as an experiment in order to get a line on what the truck could do, had made such a poor showing that it had been decided to postpone the purchase of a fleet until some future—and very indefinite—time; that the firm believed thoroughly in the future of the motor truck, but was firmly convinced that the experimental period was still unfinished, and so forth and so on. Later they would be pleased to re-open negotiations—"Like h—l they will!" muttered the D. E.—and in the meantime they would be pleased to know what price they could obtain for the machine on hand, which was really in very fair condition, having done comparatively little work.

"Rotten!" ejaculated the Inquisitor, feelingly, after he had mastered the contents of the letter. "Rotten, with trimmings and extras on the side! But why didn't you put in a machine that would do their work? They seem to be afflicted with a regular old canal-boat on wheels."

"That's just the rub," replied the D. E., gloomily. "It's a good machine, and it can do their work all right, and we would have landed them for a fleet of at least eight or ten if it hadn't been for the question of drivers. That's what killed the whole business."

"Drivers!" exclaimed the Inquisitor. "I thought any idiot could drive a truck."

"No. Not any idiot; only some brands of idiot." By this time the D. E. was sitting on the back of his neck with his feet among the pigeonholes—his favorite attitude when dejected. "I'll tell you the whole horrible tale and get it off my chest.

"You know, I have nothing to tie me to any particular manufacturer unless I believe in his machines and think they can make good under proper conditions—which means that I can sell them so that they will stay sold. Now, I learned that Jones, the senior partner of the firm of Jones & Co., had been evincing a great deal of interest in motor trucks and that he had even gone so far as to allow himself to be approached by one or two salesmen. I saw him myself, wormed out of him a lot of information, and managed to work out a set of figures that really made things look good for motor trucking. Naturally, I know what my machines will do in work of the sort Jones & Co. are engaged in, and I was able to show the old man something that gave me the inside track. He consented to put in a machine just to see how it would run, and if it did well he would put in a fleet.

"He was very particular on one point, however. 'We have a force of men who have been with us for years,' he said, in his pompous way, 'and I won't have them thrown out. The only way to keep them is to train them to drive the motor trucks. That can be done, can't it?' I assured him that if the men were of the right sort it could be done. 'All right,' he replied. 'When the machine is ready let me know and I'll have a man picked out for the job.' Well, I wish you could have seen the man. He may have been all right as a driver of horses; probably he was born and brought up in a stable and couldn't help being a good man in his proper field. But as a motor truck driver he was absolutely hopeless. The machine is a battery truck. Every time Tom moved the controller handle he muttered 'Whoa!' or 'Giddap!' as the case might be, and in an emergency he would pull backward on the steering wheel and yell 'Whoa!' and sit and wait for the car to stop. At first he showed a strong desire to understand all about the motive power, and I believed he was in earnest. I tried to show him the way to read the meter and how to figure his volts and amperes and kilowatts. But I got no further. It seems that he had an inveterate hatred of Italians, and the moment I pronounced the word kilowatt he pricked up his ears. 'Kill-a-wop?' he howled, 'Kill-a-wop? You bet! Haw, haw! Ho, ho! Kill-a-wop! That's the name of this here machine.' And that was as far as I got, for he refused to do anything but roar at his own joke and immediately lost all his pretended interest in the meter. Finally I had to go to the old man and explain as diplomatically as possible that the man probably would do all right when he had had enough training, but that it would take some time to get horses out of his head and that a man ought to be put on who could pick up the work quickly. Old Jones looked at me with unfeigned suspicion.

"'I thought you said any man could drive your machines?' he said, looking at me over the tops of his spectacles. 'Tom's team is the best team in the stable; he can't be a fool or he couldn't keep them in good shape and get the work out of them that he does.'

"I tried to explain, and finally Jones consented to give me another man, but he didn't like it at all, and I could plainly see that he was disgruntled. The new man was an improvement, and so far as the actual driving of the machine was concerned he was all right; but his trouble was that the slightest thing out of the ordinary robbed him of all his wits and he could not think, though he never was at a loss when anything went wrong with his horses. But the deposed driver immediately began to make trouble. He told the new man that I was part Italian because I got him 'sacked' when he joked about 'wops,' and that made it hard for me. The men cared nothing for the truck, for though they had been told that if more trucks were installed they would be put on as the drivers, they were of a suspicious turn of mind and were inclined to believe that they would be fired and replaced by chauffeurs—a belief that the first driver helped along considerably, holding himself up as an example.

"To make a long story short, I couldn't get a thing done with the truck. It was abominably treated when my back was

Digitized by Google

turned — smashed against string-pieces, pounded over railroad tracks in the yards, where a good deal of work had to be done, run for miles with the brakes partly on—all with a low cunning that was admirable, in its way. The reports of the men and the foremen were that the truck was all right when there was an expert handling it, but that it was too blankety blank delicate, for when a strong man touched it something busted. Old Jones believed his men and refused to believe me. 'The thing's broken,' he would say, 'and the driver says it just let go while he was running along an ordinary street. Why should he lie about it? It's to his advantage to get a better job if he can, and he would get more money as driver of the machine than of horses. Seems to me the machine is too weak.' I tried being perfectly frank and explaining the situation exactly as it was; but the old duffer kept up that everlasting cry, 'Why should the men try to spoil good jobs for themselves?' I tried to get him to let me put my own man on, and he went so far as to consent to week's trial; but at the termination of a first class six days' work he informed me that he was convinced that while the machine would do well in the hands of an expert, it was no good in an ordinary man's hands, and he couldn't afford to pay mechanical engineers to haul his stuff.

"Well,—well, here's the result!" The D. E. flipped the letter disgustedly onto the desk, removed his feet, straightened up in his chair and looked at the Inquisitor with a what-would-you-do-about-it air.

"It reminds me, in a way," said the D. E., after waiting for comments and getting none, "of another case where the driver problem made trouble; but this time it ended differently. You know Wilson, of the Empire Emporium? Well, that's the man. He's rather excessively good-natured and sometimes it's taken advantage of. He needed a big truck for his wholesale delivery work, and as there was a good deal of long-distance work I sold him a gasolene machine on condition that if it could not be made to show a saving in excess of a stipulated amount I would buy back the machine for the original price minus hire for the time it was in use and an allowance for wear and tear. The conditions suited me all right, because I knew the truck was well able to do the work. Wilson agreed to hire a good man, let me pass on his qualifications and work him under my demonstrator for a week or so. That certainly sounded most satisfactory.

"Wilson, in casting about for a man, applied to one of his old cronies, who instantly recommended his brother-in-law who, he informed Wilson, had been a mechanical engineer but had lost his health and was consequently in reduced circumstances, and willing to take any sort of a job for a while, and so on. Incidentally, he had recovered his health. He knew how to drive, for he had once owned a car of his own. I talked to the fellow and found him remarkably intelligent—I believe he knew more about cars than I did, in fact. I couldn't understand why he was looking for a job as chauffeur, but he certainly had the necessary qualifications, and after seeing him run the truck for a trip I agreed most heartily to his engagement. I sent my man with him for a few days only, and congratulated Wilson and myself on having made a find.

"I wasn't long before queer things began to happen. Three times in one week old Graham got stuck for gasolene, and another time his motor ran out of oil and reached the garage on the point of 'freezing.' On two separate occasions he telephoned my office that something that he was unable to locate was interfering with the proper running of the motor, and wouldn't my man run down and have a look? He had been working nearly all night the night before and was going to get a little rest. On both occasions my man went down and found little fool things, such as cracked spark plugs, or ignition wires disconnected, or something equally trivial—I forget just what, but things that old Graham could have found and fixed with both eyes shut and his hands in boxing gloves.

"The indications pointed to booze, according to my way of thinking, but the old codger was never seen under the influence of liquor, and there was nothing in his appearance or even in the smell of his breath to indicate that he imbibed. I tried to catch him, but couldn't. The engine had a good many queer spells in the meanwhile, and Wilson didn't like the frequent and inconvenient delays. I tried to explain the matter to him, but he had such an abiding faith in the man who recommended Graham that I could make no impression whatever on him. So I 'laid down' and waited for a chance; I was becoming more certain that Graham was hitting it up on the quiet, for as winter weather came on the engine showed more and increasing crankiness. I had several more or less disagreeable interviews with Wilson, who finally became exasperated and wound things up by saying that in his own private opinion the d—d truck was no good and that I was trying to make a 'goat' of the driver; but that if I could prove my suspicions to be correct he would bounce Graham on the spot and let me put in a man myself.

"That sounded pretty good to me, and I waited and schemed; but, as it happened, I might as well have saved myself the trouble of making plans for the downfall of Graham. One bitterly cold day Wilson's operating office received a telephone message that the truck was at such and such a street, broken down, with the load still on board. It happened that there was no one in the Wilson office who was of any use in such an emergency, so they telephoned to me. I got my things on and posted up to the place as fast as I could travel, and what do you think I found?

"The truck was standing at the curb, a quarter of a mile from its destination, and Graham was nowhere in sight. Investigation proved that the engine cylinders were rusted red, as if they had been in a hot fire; it was stuck hard and fast and the crank failed to budge it. Also, all the water in the radiator was frozen solid, which had knocked the cooler galley-west, and two of the cylinders were cracked from the same cause. I hunted around for Graham, but he was not to be found, and no one had seen him since the truck arrived, three hours earlier. Leaving a couple of teams to transfer the load, I found out where the driver lived, went there and found him in his room, asleep with his working clothes on and snoring the snores of the very drunk. Just to be mean, I got Wilson to come and look at him where he slept, and the old man was so mad that he tried to wake up his erstwhile favorite to fire him, as promised, on the spot; but it couldn't be done, so the discharge was written to a slip of paper and pinned to Graham's shirt. Graham was never seen again, so far as I ever heard.

"We had the truck towed home and found that it had been run without water and without oil—not a drop of either—until the cylinders had overheated and the pistons seized. Then Graham dumped in some water, but, of course, couldn't start the engine, so he went and got a drink to fortify himself for further exertions, and it took so long that the engine cooled off to the freezing point. Graham, according to a witness, took one look at the motor and then made straight—or, rather, as straight as he could—for home. All the cylinders of the motor were destroyed, the bearings throughout the motor cut to pieces, the crankshaft scored so deeply in the bearings that it was good for scrap only—there was nothing left that was any good but the crankcase and the magneto. It meant a whole new engine and a new radiator.

"Wilson came up like a little man; bought a new engine and radiator, paid for having them put in and had the truck generally overhauled at his own expense—not that he shouldn't have done all this, but the point is that he did it cheerfully, which is more than most people will do. I put a man on and the old mill has been working like a top ever since, and if nothing happens I'll sell a couple more to Wilson within the next few weeks. And now when I talk Wilson always listens with both ears."

"Well," said the Inquisitor, waiting for a moment after the D. E. had stopped talking, "what's the moral?"

"The moral is that when a man who has tried a truck says it's no good, you can't always tell from what he says whether it is or not," said the D. E.

Using Rosin to Aid Soldering Operations.

Common rosin dissolved in turpentine makes an excellent soldering fluid, and one that is particularly useful in electrical work because it will not corrode the metal upon which it is used. It may be applied with a little swab on the end of a stick.

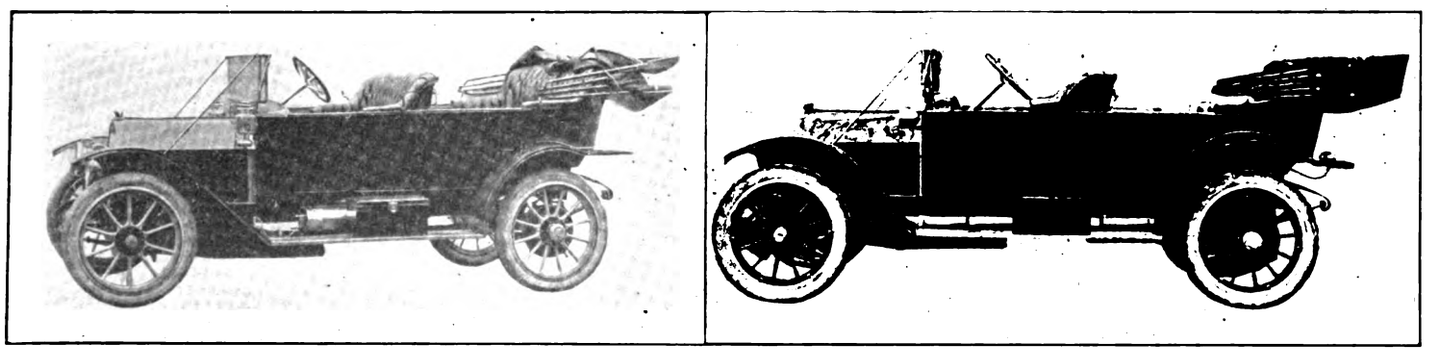
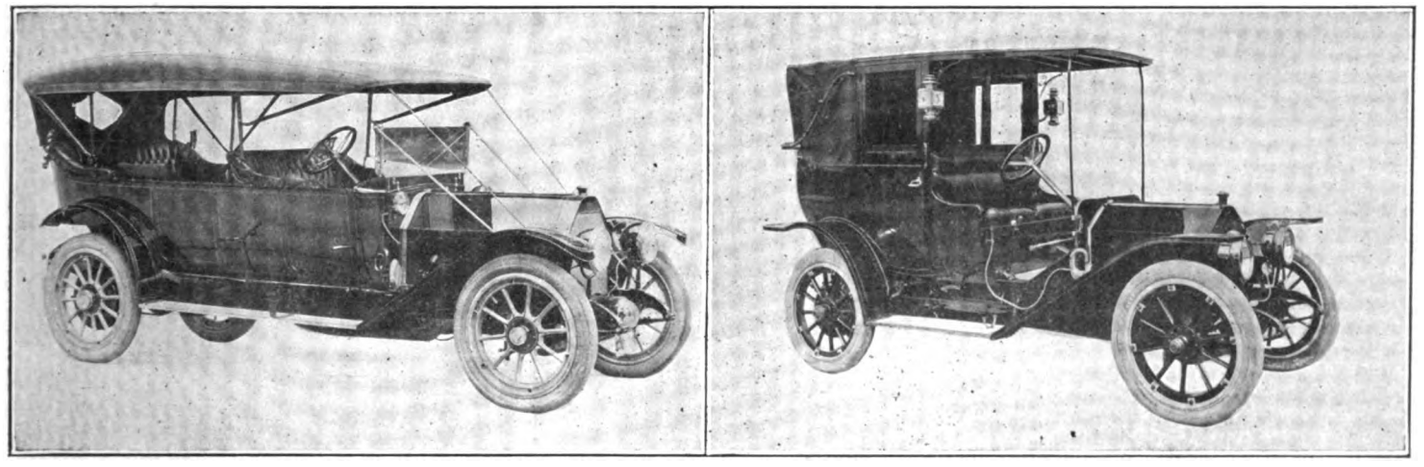
PULLMAN ADDS POWER AND COMFORT

Refinement Carried Out Along Those Lines —Wherein the "Fours" and the "Six" Show the Good Results.



As is but natural in the productions of a manufacturer whose cars have earned a reputation for themselves, Pullman cars of the newer series that will go to make up the line for the coming year have changed but little from their immediate predecessors. A general refinement has been made, as a matter of course, in which the manufacturers, the Pullman Motor Car Co., York Pa., have centered particular attention on the spring suspension of its cars. To this end all springs have been lengthened and the three-quarter elliptic rear springs which have served in the past have been changed to scroll three-quarter elliptics, and this constitutes practically the only material alteration that has been made.

As heretofore, four chassis are included in the line; three of them are four-cylinder models, and the fourth is the six-cylinder model which made its initial appearance late last Fall, just prior to the national shows. In line with slight increases in power which have been made possible by the smoothing down that has been effected, the designation of two of the four-cylinder models, the 4-30 and the 4-40, has been changed to 4-36 and 4-44, respectively. The six-cylinder model also has been newly christened, for the same reason, and hereafter will be styled 6-66.



The motors in all four chassis follow the general lines that were laid down by the Pullman company several years ago, no reason for change in design or construction having been found. All have their cylinders cast in pairs, with the valves, which are on opposite sides, carefully enclosed further to reduce valve noises and to prevent the ingress of dust and dirt and other objectionable matter. The bore and stroke in each case remains the same, the measurements being 4 1-16 x 5 for the 4-36, 4½ x 5 for the 4-44 and 4½ x 5 for the 6-66. Valves, however, have been slightly increased in size, which accounts in a measure for the increase in power available. No little of the increase, however, is due to the modified oiling system which has been adopted, and which, it is calculated, will effect material savings in oil while at the same time ensuring efficient lubrication and the absence of smoke. As heretofore, lubrication is by the automatic level splash system. But the eccentric pump which circulates the oil and maintains the splash compartments full now is regulated from the dash instead of from the side of the crankcase, as in the past. Thus it is possible for the driver to increase or decrease the supply of oil to the crankcase to suit the requirements of engine speed without the necessity for stopping the car or leaving his seat. Incidentally, the oil capacity in all the models has been increased.

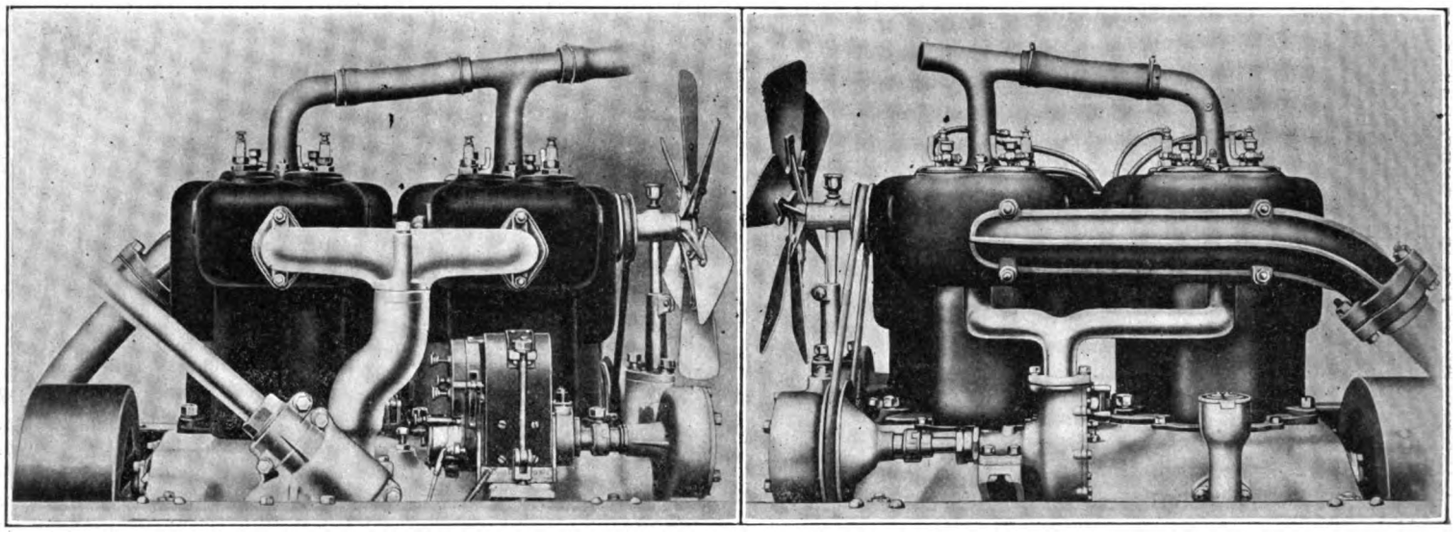
Another of the factors which has a direct bearing on the increase in power which has been made possible concerns the reciprocating parts, which all have been lightened, particular reference being made to the wrist pins. Such lightening as has been effected is such as to leave an ampler factor of safety, however, and its only effect is one which genuinely may be classed as beneficial. Cooling is by water, circulated by a positively driven centrifugal pump; except for a slight increase in the size of the radiators in all models, whereby the water capacity is made greater, no change has been made in the system. Ignition is effected by Bosch high tension magneto exclusively, the system being of the well-known dual type that has become familiar by reason of its widespread adoption.

On the two larger models, namely, the 4-44 and the 6-66, the complete electric lighting system which last year was adopted is retained substantially without change. That is to say, there has been no change in the component parts, though the method of driving the generator has been made more positive and now is effected by means of a chain of the "silent" type. The electric tire vulcanizer which forms an item of equipment on the 6-66 and is an exclusive

TWO PULLMAN 4-CYLINDER MODELS IN THEIR LATEST FORM—THE "4-36" AND THE "4-44"

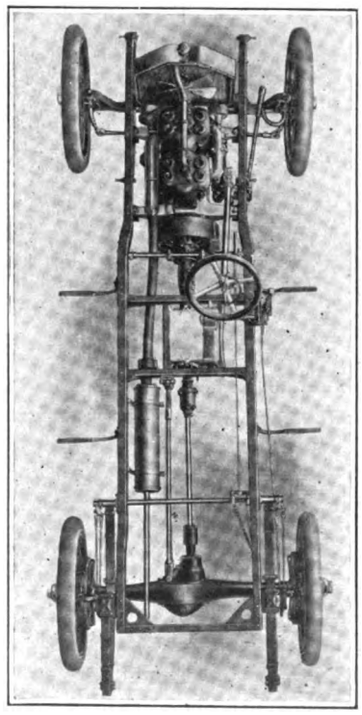
PULLMAN "6-66" IN TOURING TRIM AND THE "4-36" WITH SMALL LANDAULET BODY

Digitized by Google



feature of the Pullman line is retained. The remainder of the electric equipment includes the usual complement of head, side, tail and dash lamps. The carburation system remains unchanged, except that a dash priming device has been added. All the motors are equipped with starting devices.

The similarity which obtains in the case of the motors is continued through the remainder of the cars, the only difference being in the wheelbase, and the size of parts, of course, and in the change speed mechanism. The 4-36 is equipped with a three-speed selective system and the other models all have four-speed systems, the high gear in each case being the direct drive. All models have leather-faced cone clutches of large diameter, the size in the case of the 4-44 and the 6-66 having been increased 2 inches and now being 18¾ inches. By reason of the rearrangement of the springs and other refinements, the drive line has been made practically straight and much power thereby conserved, the saving being effected in no small way by the careful manner in which the pins and blocks of the universal joints and the shafts in the change gear mechanism now are ground to within one-quarter thousandth part of an inch of size.



The front axle remains of the I-beam type with Elliott steering knuckles. The rear axle, which is enclosed in a pressed steel housing, is of the standard full-floating type and is mounted in annular ball bearings. Brakes in each case are mounted on the rear wheels and are of the internal expanding and external contracting variety, proper leverage being allowed to reduce the fatigue of driving and ample adjustment for wear provided. Treads, or rather the distance between either pair of wheels, is standard—56 inches—and the wheelbases are 118 inches for the 4-36, 122 inches for the 4-44 and 138 inches for the 6-66.

As regards the bodies, it scarcely will be necessary to point out that they are of thoroughly up-to-date design in which the comfort of passengers has been combined with an attractiveness of outline that is quite in keeping with the mechanical perfection which Pullman engineers have striven for and obtained. Control in each case is from the right side, with the gear shift and emergency brake levers at the driver's right hand. The steering gear is of the semi-reversible worm and sector type, with the engine controls within the periphery of the wheel though separate from it and stationary. On the 4-44 and the 6-66, the diameter of the wheels has been increased slightly to permit of greater leverage and easier action. All the bodies are of wood and metal construction, and on any of the chassis may be had in either roadster, small tonneau, five- and seven-passenger touring, coupe, landaulet and limousine form.

With any of the open body styles the price of the 4-36 remains $1,675, of the 4-44, $2,150, and of the 6-66, $2,750. These prices include complete equipment, as a matter of course, the list being, complete electric light system, top, windshield, speedometer, horn, tool box, foot and robe rails, demountable Q. D. rims and the usual complement of tools and spares. The 6-66, as already mentioned, also carries with it an electric tire vulcanizer for use in conjunction with the lighting system. In the case of the 4-36, the place of the electric lighting system is taken by a Prest-O-Lite tank with the usual complement of gas and oil lamps.

PULLMAN 4-CYLINDER CHASSIS

Crook Gives New Twist to Tire Theft.

Great as is the quantity of genius which is every day perverted or thrown away, so fas as any good result is obtained, nothing furnishes more striking illustration of the practice than the criminal world, in which the new schemes constantly being devised to separate someone from their possessions seem without end. Elgin, Ill., for instance, has been visited by a "crook" who, while a tire theft is nothing new, has a peculiarly original twist to his plan of action. The man in question visited Ziegler Bros.' Garage and asked to see some tires, evidently, from later actions, looking for a size or style of which but one or two remained in stock. He found a tire of which the garage had but one and then, of course, said this was just what he wanted; only he needed two. He gave the name of a well known driver as the purchaser, and said he would take the one tire, ordering the other "rushed" over as soon as it could be secured. The second tire was delivered later, to the surprise of the driver, and returned as "not ordered," to the surprise of the garage men. Ziegler Bros. believe the best place to search for their tire would be among Chicago "fences," basing their belief on the fact that innumerable tires so secured were sold in second-hand stores and pawn shops for a small price.

SYSTEM—AND GOOD COMMON SENSE

Advantages and Disadvantages of too Much or too Little of Either—Also, the Employe's Duty.

The sales manager was mad—not in the good old original meaning of the word which appears first in the dictionary, but according to that popular American colloquialism which indicates a rather high temperature in the vicinity of the seat of emotions; in other words, he was suffering from a serious attack of choler. Mad, in its original and real meaning, was what he applied to the general manager, the officers of the company, the managing committee and nearly everyone else except the sales manager. He didn't tell them so, because that would not have been diplomatic, but having lost his temper he went in search of it and thought the best place to seek that vanished possession would be in the whir and hum of the factory.

As soon as he steamed across the factory yard and neared the test shed the chief tester knew something was wrong, and, as the sales manager exploded with an almost incoherent train of derogatory characterizations of "system," the chief tester smiled. Dipping his fingers into a pail of water, he sprinkled a few drops on the forehead of the angered one and said solemnly, "There, Jim, now you're cooled off." It had its effect, and the sales manager consented to smile, but he simply had to rid his system of the troubles that clogged it.

"What got you into such a stew this fine morning?" asked the tester.

The ludicrousness of the triviality of the cause appealed then to the salesman as he meekly answered, "A lead pencil."

"A lead pencil! Pretty small thing to break up a morning's work, isn't it?"

"It is and it isn't. It's more than that; it's the blamed system in this establishment. Here I want a pencil, and I no sooner go after it than I find the conglomerated fool thing System has taken another new tack. I go to the stockroom keeper for a pencil and he asked me if I had an order. 'Order!' I said, 'what order?' and he explained that I had to have an order from headquarters to get anything from the stock room. I went to the general manager and he told me to make out an order on a blank and he would send it on to the managing committee. After they O. K. it and the president and a few more put their initials on it, it comes back to the general manager, who turns it over to me, and if I haven't gone out and bought a pencil by that time, I can get one by presenting the ticket to the stock keeper. But I want that pencil this morning and I can't get it until afternoon or to-morrow."

"Here, I'll give you a pencil," said the tester, as he drew a greasy stub from his overalls' pocket.

"O, don't try to be funny—it's no joke," was the pettish reply. "I suppose I could take your pencil, but have I got to run out here and get a dirty looking article like that every time I want a new pencil? I'll tell you right now there's too much system here; the whole place is wrapped up in it."

"You can't run a business without system, can you?" queried the tester.

"No," was the retort, "but they ought to pay more attention to business and less to system. Who ever heard of big officers in a factory like this wasting their time over a pencil that doesn't cost over a cent. And look at me: I've lost my head and will have wasted an hour, and that is worth—let's see, nearly two dollars and a half. I know, of course, system is all right, but it is like booze and some other vices; it ought to be used with moderation.

"It's not only this particular instance of the pencil, but you find it everywhere. How many times has it almost lost a sale? More than once I have had a $5.000 car standing on the final assembly floor waiting for some little part, like a windshield or horn, while the part intended for the car and drawn out of stock for it had to go back to the factory because there was some slight defect in it, and the car had to wait for perhaps two weeks, while the owner was yelling like a wild man and wondering why we didn't send his car on schedule, as we agreed. I have spent hours smoothing out these complaints.

"Then, at the same time this car was being held up, there were cars further down in the line, with identically the same parts on them, and a shift could have been made and the first car gotten out of the way, and if the defective part hadn't returned by the time this next car reached the head of the line, another shift could have been made and things kept moving; the factory wouldn't have any great trouble keeping track of things, and it certainly would have given satisfaction. Once, we had an owner who had bought our cars for several years, and various things had not caused him to be in the happiest frame of mind, and when there was a prospect of his car being held up for a week or so I was sure he would cancel the order if he didn't get it, for he had written me he wanted to start on a tour on a certain date with a party of friends, all of whom had cars. I persuaded the foreman to make a shift and get the car out on time—but never again! We saved the sale, but I almost lost my job and the foreman was given to understand from whom he was to expect orders in the future. And that person who is to give him orders isn't the sales manager.

"Lots of times a whole line of cars which are coming through from a certain lot of stock are held up because some of the parts are not finished. The system works fine, because it keeps the lot together and it leaves the factory at the same time. But what I never have been able to discover is why the system isn't placed to work on the other end and followed up, so that the work will go along as it should and these parts be ready when the cars get to the final assembly floor. It's like a political campaign that is run with vim in spots and a big vote is piled up with good results, but the falling down is so emphatic elsewhere that the total result is disappointing.

"I don't know which is worse—a factory that is all system or one that never had a system. We won't mention any names, but I know one factory where the proper running of things is put up to certain men. No one asks how they do it, but they are expected to see that things come through on time and correctly; of course, these men must have some system of their own, but as long as it works no one tries to tell them about some other. There are times when things go wrong, as they undoubtedly will without a good general system, but good, efficient men, to my mind, are worth more than books full of system.

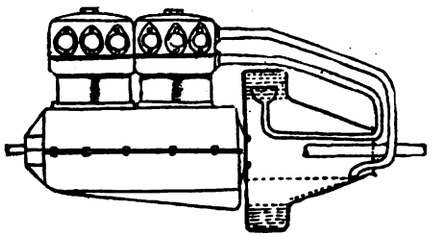
"Now, our system, so far as the system goes, is all right as a general rule, but too much is centralized. The stock keeper is getting fair wages and is an honest, capable man; so why couldn't he take care of his stock. He knows how many pencils every man is entitled to, and if any one began to go too heavy on the supplies the stock keeper could investigate; or what would be the matter with the head of every department approving the orders for supplies in his domain and let it go at that? Instead, here is the general manager, getting $10,000 a year, wasting his time O. K.ing orders for penny pencils. If a man is competent to manage a department, why isn't he competent to order what supplies he needs? If the boys up front want to economize there is no one who more gladly would jump in than we and fight to keep down expenses; but instead of that the high-salaried men are worrying over too many little things, when they have subordinates who are paid for doing just that thing.

"I don't mean to say that system is wrong. I believe in it with my whole heart, but I do also perform a little worship now and then for the God of Common Sense, and he's a pretty good old pal to have in business with you."

"I dare say you're right," rejoined the tester. "Of course, we don't stack up against the system like you do, but I've heard all kinds of arguments on the proposition. All we have to do is take care of the testing end, although we get a little system now and then, I always try to keep things running right. On the other hand, this company pays me pretty good money to do good work, and I think it's up to me to do it as they want it done, and if they tell me they would like to have the cars tested out backwards on the road and the motors run on three cylinders in the test shed, I think it's up to me to do it. Besides, there may be reasons for a lot of peculiar orders such as those, and there

Digitized by Google

are a few things about the inside of the business that I don't happen to know."

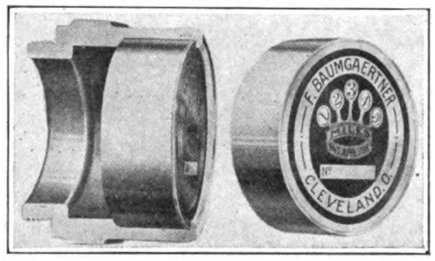


"That's common sense, too," said the sales manager, as if the tester's view of things might not be so bad in the sales department. "Anyway, thanks for those drops of water—and maybe I can get along with the system. I surely ought to be able to do so, if the rest can. Also, as you say, I'm not running this business. I'm holding down a job."

As the sales manager started back for the office the tester called, "Here, don't you want this pencil?"

"No," was the answer, "I guess I didn't need it as bad as I thought I did. A wait won't hurt."

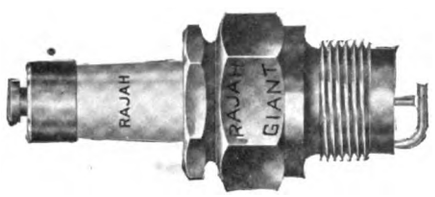
Using Flywheel for Cooling Purposes.



According to the views of C. Constantini, a Roumanian engineer who recently perfected and placed on the English market a carburetter which it is claimed is efficient when using either kerosene or distillate, the proper location for the radiator of a motor is in the fly wheel. His idea of how it may be done is expressed in a patent cov-

ering the arrangement shown by the accompanying picture. The flywheel of the motor is cast hollow with a tapering projection on the front. Into the funnel attachment pass the leads to and from the jacket, the former having a flared end which serves to collect the water which distributes itself around the hollow channel of the flywheel when the latter is in motion. On the return, the water is allowed to trickle down the inclined sides of the tapering projection, whereby, it is said, it is sufficiently exposed to the cooling effects of the air to be reduced to the proper temperature for return to the jacket.

Gravity Odometer That Comes from Ohio.

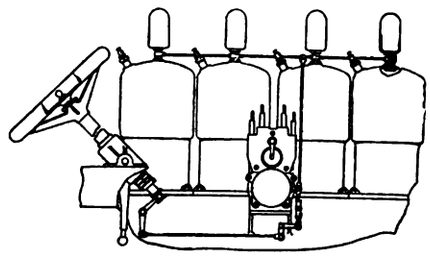


To check the performance of any commercial vehicle, it is absolutely essential that an accurate record of mileage be kept, for it is on this factor that all computations affecting efficiency, depreciation, cost of operation and general all around ability must be based. Obviously, it is not sufficient that the mileage be known to within three or four miles, nor it is permissable, for accurate results, to attempt to figure actual car mileage from road maps even when the route of the vehicle is laid down and adhered to as closely as possible. It is not possible for any vehicle to continue for any great length of time in a perfectly straight line, and it is the deviations necessitated by poor spots in the roads, obstructions such as horsed vehicles, for which the truck must turn out, and the inevitable detours which frequently become necessary by reasons of road construction, that make up the discrepancy in mileage which may affect efficiency figures to an extent that is unsuspected. It was to eliminate the necessity for all computations to determine actual vehicle mileage and to provide a means whereby accurate record of the number of miles covered might be preserved from day to day that the Coronet hub mile recorder for trucks was developed. It is the

product of E. Baumgaertner, of 2344 East 105th street, Cleveland, O. As may be seen by the accompanying picture, the device is small and compact and is designed to be attached in place of the standard hub cap. In fact, it is pointed out, its appearance is such as scarcely to warrant detection of its presence; it is made to resemble any hub cap, and when in place projects not more than five-eighths of an inch further than the hub cap which it replaces. In construction it is similar to several other devices of the same general nature which are on the market and operates solely by gravity, there being no connection whatever between its mechanism and the axle of the vehicle. It is guaranteed for a period of two years.

Rajah Produces Spark Plug for Trucks.

That a chain is no stronger than its weakest link is an axiom which is time hon-



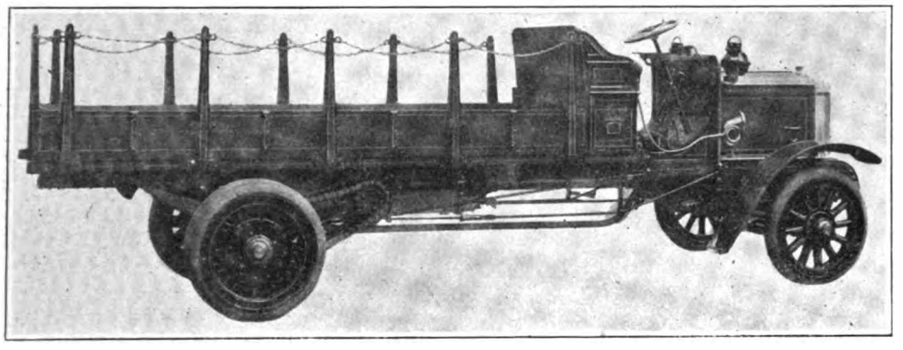
ored. The weakest link in the commercial vehicle, according to the Rajah Auto-Supply Co., of Bloomfield, N. J., is the spark plug, which often is not equal to the task imposed upon it when in service on a commercial car, although perfectly capable of giving a good account of itself in the less strenuous pleasure car service.

With this in mind the Rajah Giant plug, shown in the accompanying picture, and which has been designed expressly for use where excessive vibration and general rough handling are common. The name Giant relates more to the characteristic sturdiness of the product than to the size, for the measurements of the latest Rajah plug are but very little greater than those of the regular product. Not including the clip terminal, which is an "added feature," but four parts enter into the construction of the plug, a steel shell carefully threaded with S. A. E. standard threads, a brass bushing, copper asbestos gasket, and a special imported porcelain. All parts save the porcelain and wire electrodes are made in the Rajah factory on special Brown & Sharp machines, which insures accuracy and interchangeability of the parts, which, coupled with the fact that so few parts are used, makes the removal of the core for cleaning or adjustment a simple matter.

Starter That Operates from Steering Post.

Working on the theory that if one has to perform a "contortion act" in order to reach a pump handle and inject a charge of explosive mixture into the cylinders, then give another twist to press the button which controls the ignition of the charge, not much comfort can be obtained from the application of a starter of the ignition type,

Unterberg & Helmle, the widely-known magneto manufacturers, whose factory is located in Hamburg, Germany, have developed an ignition starter designed to eliminate manual labor in so far as the pump is concerned; the only movement necessary for the starting operation is the turning of a small lever positioned with the spark and gas levers on the steering column.



The device, which is shown by the picture, consists of four pressed steel chambers which are positioned one over each cylinder of the motor and are connected therewith by means of a passage. Stopcocks which are provided in the passages are linked together so they can be controlled in unison by the proper manipulation of a lever which is placed on the steering post. The movement of the lever also is communicated to the armature of the magneto, so that the use of a coil for starting is unnecessary. After the motor is switched off, the stopcocks are opened and a supply of gasolene and air in suitable proportions is forced into each of the chambers and retained by means of checkvalves. The cocks are closed when the fly wheel has come to rest, so that the mixture is retained under pressure. A movement of the starting lever at once opens communication with the cylinders and produces a spark in the cylinder which is on the firing stroke.

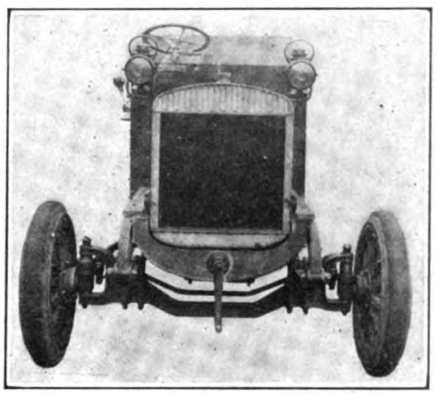
DRIGGS-SEABURY ADOPTS VULCAN

Chooses that Name in Formally Entering Truck Trade on its Own Account—Its Line Varied and Complete.

Although the Driggs-Seabury Ordnance Corporation of Sharon, Pa., has for a number of years produced commercial vehicles for others, among them the American Commer truck, and has been and still is engaged in the manufacture of frames and sundry other parts which go to make up trucks, it at last has commenced the manufacture of a line of trucks of its own which will be marketed under the name "Vulcan." Whether they will be marketed through agencies has not been definitely decided. In the meantime the company is holding the reins in its own hands. The trucks themselves are of standard construction throughout and reveal nothing that is radical or startling, the sizes at present ready for the market including vehicles of 3, 4, 4½, 5 and 7 tons capacity. Eventually, the line will be further rounded out by the addition of 1, 2, 6 and 8 ton sizes, these being at present on the draughting tables and in process of building.

SIDE VIEW OF 4-TON VULCAN TRUCK WITH STAKE BODY

All of the variously rated vehicles are of the same general pattern, the engine being located under a hood at the front, behind the radiator, thus centering 70 per cent. of the weight of the vehicle and its load over the rear axle and ensuring positive traction at trying moments, as on bad roads or when the pavement is wet. In all the trucks but two sizes of motor will be used. The motors themselves are the product of the Driggs-Seabury company, and inasmuch as they are identical except for a difference of ⅜ of an inch in the bore a description of one will suffice for both. The smaller motor, which will be used in all the vehicles rating up to five tons capacity, is of the four-cylinder vertical four-cycle type with the cylinders cast in pairs and the valves all located on the same side. The cylinder dimensions are 4⅜ inches bore and 5½ inches stroke, the S. A. E. rating therefore being 30 horsepower. The larger motor, which is used in all the other vehicles, differs from the other only in that the bore measures 4¾ inches, the rated horsepower, according to the S. A. E. formula, being 36.



In the case of the 1, 2, 7 and 8 ton vehicles cooling is effected by pump circulated water, thermo-siphonic action being relied upon in all the others. All have Bosch dual ignition supplemented by a coil and 6-volt storage battery and a combination automatic level pump-over splash lubrication system in which the oil is maintained constantly in circulation. In order to eliminate the possibility of accidental damage to the motors through frame weaving they are supported at three points in the chassis frame.

All the motors are regularly equipped with centrifugal speed governors which are set to restrict the speed of the vehicles up to three tons capacity to 18 miles an hour. The other speeds are as follows: 8-ton, 10 miles an hour; 7-ton, 12 miles an hour; 6-ton, 14 miles an hour; 4- and 4½-ton, 16 the engine to the road wheels through the miles an hour.

Power in each case is transmitted from intermediary of a leather-faced cone clutch. selectively operated change gear mechanism locatd in the waist of the chassis and heavy side chains. In all the trucks up to four tons capacity the change speed mechanism is of the sliding gear type, while in the others the gears are constantly in mesh and are engaged by means of sliding dogs; the 6-, 7- and 8-ton trucks have four forward speeds and reverse, and all the others have three forward speeds. The side chains are not enclosed in chain cases. Two sets of brakes are provided on all the chassis, the service set being located on the jackshaft and the emergency set on the rear wheels. The differential is integral with the change gear mechanism, and on the three largest vehicles in the line is equipped with a differential lock.

The wheelbase of the 1-, 2- and 3-ton models is 144 inches and provides a loading space behind the driver's seat of 123 inches. In the vehicles of from 4 to 6 tons capacity the wheelbase is 162 inches, providing an available loading space of 144 inches and a loading space of 146¾ inches. Springs in each case are semi-elliptic both front and rear and are properly proportioned to the load. By way of providing ample tire capacity and to facilitate repairs and replacement, all rear tires are of the dual type and wheels, both front and rear, are fitted with standard S. A. E. detachable rims. In all but the 7- and 8-ton vehicles the tires sizes are the same front and rear, the vehicles up to 3 tons capacity being fitted with 36 x 4 tires; 4-ton, 36 x 5; 4½- to 6-ton, 36 x 5½. On the 7- and 8-ton trucks the front tires measure 36 x 6 and the rear tires 42 x 6 inches. The wheel track in each case is standard—66 inches.

In common with the majority of the other parts that make the trucks, the steering gear is produced by the Driggs-Seabury company, and in each case it located at the right side with the control levers at the driver's right hand. The list prices of the five chassis that now are ready for distribution are as follows: 1-, 2- and 3-ton, $3,600; 4-ton, $4,000; 4½-ton, $4,500; 5-ton, $4,750; 7-ton, $5,600.

VULCAN FRONT AXLE CONSTRUCTION

Why Speedometer Dial Hands Oscillate.

It is one of the peculiarities of many types of speedometers that directly the car is driven over rough roads the dial hand oscillates more or less wildly back and forth and makes reading the meter practically impossible. The trouble becomes most pronounced when the car is driven at speed, and this fact in itself should suggest the cause of the inaccuracy which seldom can be traced to imperfection of the mechanism of the instrument. Instead, it is caused by the front wheel bouncing over obstructions in the road. When a car is driven at high speed and one of the front wheels passes over an obstruction with sufficient abruptness to cause the wheel to jump off the road, its rotative speed momentarily is increased and this, in turn, causes a corresponding movement of the dial hand of the meter. Plainly, there is no remedy for the trouble other than shifting the speedometer drive from the wheel to some other portion of the car, as the propeller shaft or one of the change gear shafts, for instance. In some cases, where a car is not fitted with shock absorbers, the addition of these accessories may effect a cure and, in any case, should alleviate the trouble to a certain extent.

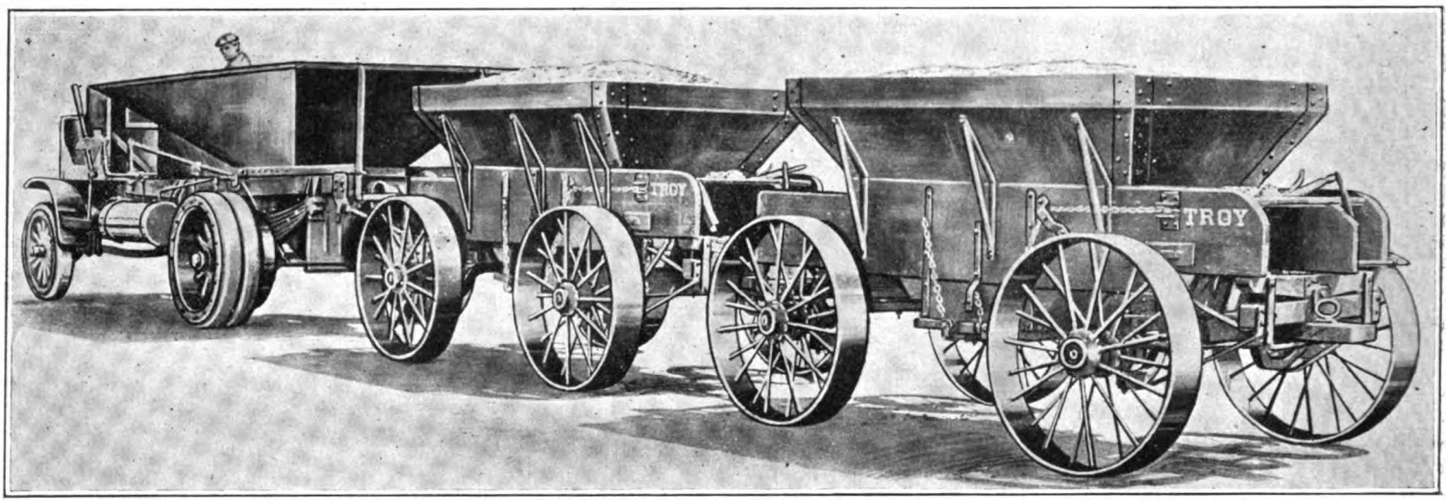
TRUCK DOES WORK OF 20 HORSES

Six-Ton Vehicle and Two Tractors Equal Ten Teams at Half the Cost—Sioux City Road Work.



Though the idea involved in the use of one or more trailers drawn by one powerful motor vehicle, thus making of the unit a road train, has made a deep impression abroad, where "trains" consisting of even four heavily laden trailers drawn by an immense steam tractor are common enough sights, it is only comparatively recently that this form of transportation has been attempted or adopted to any extent in America. Gradually, however, the popularity of this method of freight handling is increasing, the increase being proportional as the economy and worth of the system becomes established.

The progress of a road train of this character necessarily is slow, for though the driver of the tractor has all the vehicles in tow under his control, greater circumspection in driving is necessary in order to avoid interference with other vehicles and also because of the weight of the train. It is an undisputed fact that there is a load capacity for any commercial vehicle which it is inadvisable or unsafe to exceed. That is to say, there is a well-defined limit to the actual weight which the vehicle may be expected to carry with economy and safety. But if a vehicle is loaded to its full capacity there still remains a certain surplus of power and tractive effort which, under ordinary conditions, advantageously may be utilized in other ways. Naturally, the simplest way and the way which suggests itself the first is to cause the vehicle to draw another behind it. and it is herein that the tractor and trailer scores, for it then is possible to transport nearly twice the weight with the same power and without the necessity for straining the mechanism of the power element, which need not necessarily carry more weight than that for which it is designed.

As an illuminating instance of the economy of this method of transportation, the record of a six-ton Knox truck and two trailers which has been made in service building roads in Sioux City, Ia., might be cited. The truck itself is a standard Knox product equipped with a special quick dumping body to facilitate the delivery of loads.

The two trailers have a combined capacity of six cubic yards of earth. During a busy season it has been possible with this equipment to transport over a 3½-mile radius 44½ cubic yards of material a day. By way of comparing this record with what might have been done with horses, it is pointed out by the contractor that to transport the same amount of material in the same time would have required not less than 10 two-horse teams, whose cost of upkeep would have been more than twice as much as the operating cost of the truck and trailers.

Nor was all the hauling done by the train on level roads. A goodly portion of it was in hilly country, where the grades varied from 3 to 7½ per cent. Naturally, such strenuous work puts a tremendous strain on the tractor, and consequently such methods and such loads are not sanctioned by manufacturers. Nevertheless, it serves to demonstrate just what may be expected in the way of service from a motor truck, provided the method of handling is efficient and the strains which are imposed on the mechanism are not such as to exceed the liberal factor of safety for which allowance always is made by the manufacturer.

KNOX 6-TON TRUCK AND TRAILERS WHICH HAVE A RECORD FOR EFFICIENCY

Drain Pipe that May Require Cleaning.

In washing cars, it is inevitable that a certain amount of oil and grease should be removed in the process and find its way down the drain pipes along with the waste water. It is to collect such accumulations, and stray pieces of cotton waste and sponge that a trap is placed in the pipes, and in order that the water may find ready escape it is advisable occasionally to remove the plug in the trap and thoroughly clean out the cavity. If the trap is not fitted with a plug and the accumulation of water gives evidence of an obstruction in the pipe line, permitting a strong solution of ordinary lye in hot water to run down the drain pipe may effect a cure.

Handling Cores Sand Will not Support.

A core that cannot be supported in the sand of a mould would seem to be a rather difficult thing to take care of; it is held in place, however, by the simple expedient of inserting iron wires in the core and extending them across the space to be filled with molten metal and into the sand of the mould. When the iron is poured it becomes welded to the wire, so that the supporting medium does not interfere with the soundness of the casting.

Aluminum Paint as Coating for Rims.

While beeswax and graphite have been recommended as a coating for rims which will permit the tire to slide quickly and easily into place, there are those who prefer a coat of aluminum paint to either. However, care should be taken to remove all rust with sandpaper or a wire brush, if necessary, before the application of the paint, for otherwise the paint will chip or flake and the result will be worse than if no paint had been applied. It is best to mix the paint thin and apply two or even three coats.

To Reduce Rain "Speckles" on Bodies.

The varnish on a new car, or a car newly painted, is liable to become "speckled" if it is rained on. Although these spots are not wholly eradicable, the application of a mixture of equal parts of raw linseed oil and malt vinegar and not a little of the always effective "elbow grease" will render the marks less noticeable.

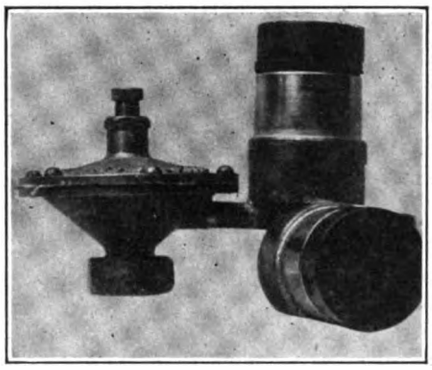
LIGHTING SYSTEM THAT DIFFERS

Blitzen Device Controls Gas at the Tank—Also Has Magnetic Valves and Practically no High-Tension Wiring.

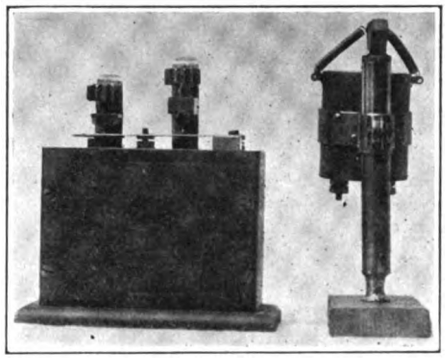


One of the difficulties of the existing type of systems which are designed to permit acetylene head lamps to be lighted from the driver's seat, and one which in the minds of not a few militates against their more universal adoption, is that it is necessary that there be a certain amount of gas pressure in the pipes leading from the tank to the dash apparatus. That is to say, after the gas is turned on at the tank its control devolves on a valve on the dash. Even when a pressure reducing valve is used to maintain the pressure in the pipes at but a few ounces, the fact remains that there is a certain amount of danger that leaks may develop owing to road and engine vibration.

It is to obviate the possibility of such leaks occurring by controlling the gas directly at the tank that the Blitzen Lighting System, manufactured in common with the Blitzen starter by the Henry Mfg. Co., of 141 West 55th street, New York City, has been developed. And so successful have exhaustive tests proven the devices to be, it is stated, that already one of the largest and most influential automobile manufacturers is experimenting with it, with a view to adopting it for use on its extensive line.

Obviously, the gas controlling valve is one of the most important parts, for upon it depends the action of the whole system. The other parts, however, are equally important and equally clever in design, the proof of the efficacy of the whole being substantiated in a demonstration by W. J. Foster, who has developed this and other electrical devices of a somewhat similar nature, notable among which are his "spark absorber" and his engine starting switch.

The principal difference between the Blitzen system and others of a similar nature is that, whereas electricity is relied upon to furnish only the spark which lights the lamps in the other systems, it is relied upon to do everything except furnish the light in the Blitzen system; in other words, the acetylene gas is turned on and off and lighted by electricity, the dash equipment merely consisting of two small buttons and a vibrator, the latter being located behind the dash or in some other convenient place. The valve which controls the flow of gas to the burners is operated by solenoids and is positive in action, has remarkably few working parts and is almost as light as the proverbial feather. As may be seen by the accompanying illustrations, it is in the form of two small cylinders which are designed to be attached directly to the pressure reducing valve, which in turn is attached to the tank outlet.



In operation, pressure on the white dash button—the black one serves to extinguish the lights—causes current from the battery to flow through one of the solenoids, raising its core and opening the gas valve to the burners. The valve is held open by an extension pin on the core of the second solenoid which, spring impelled, slips under the end of a similar pin on the core of the first solenoid. At the same time, a spark

BLITZEN MAGNETIC VALVE

is generated and ignites the gas at the burners. To extinguish the lamps merely requires that the black button be pressed when the pin on the second solenoid, which holds the valve open, is withdrawn and the core of the first solenoid returns to its normal position under the influence of a spring and closes the gas valve. The operation of the whole is instantaneous, of course, and the lamps may be lighted and extinguished almost as fast as it is possible to press the buttons alternately.

Another of the interesting features of the

BURNER COIL AND VIBRATOR

system lies in the use of miniature induction coils which are mounted directly on the burner, as shown in the illustration. The reason for the use of these tiny coils, it is pointed out, is to obviate the necessity for stringing lengthy high tension current wires from the dash to the lamps. As high tension current is exceptionally prone to escape, particularly in wet weather when the lamp lighter might be expected to be in greatest demand, it is hoped by this means effectually to remove one of the principal sources of annoyance to which such systems as a rule fall heir. The only wiring in the whole system which carries high tension current are the two wires leading from the tiny spark coils to the burners; their length may be judged from the picture. Despite the small size of the spark coils, however, they are capable of generating sparks one-quarter of an inch in length, whereas a spark one sixty-fourth of an inch in length is plenty long enough to ignite the gas. The vibrator, which is designed to occupy an inconspicuous place on the dash, is of orthodox pattern, except that a novel means of trembler adjustment is used. It is virtually a spring working on a spring, for which reason, it is claimed, unusually fine adjustment can be made and the consumption of current reduced to the minimum.

What Causes Tires to Lose Air.

Of the tires tested by the Michelin Tire Co. on cars which stop at its factory in Milltown, N. J., a full 50 per cent. are found to be under-inflated, while of the tires received for repairs nearly 60 per cent. are found to have suffered from this cause. There are many ways aside from punctures and blow-outs in which the air pressure in a tire can sink below normal, says the Michelin company in commenting on the fact. The valve may not be airtight, or if the tire is new it may expand slightly when first used, with a conesquent reduction in pressure. Moreover, rubber, while practically airtight, is not entirely so, and the air will gradually filter through into the atmosphere. Air is composed chiefly of oxygen and nitrogen. The coefficient of diffusion of oxygen through rubber is higher than that of nitrogen, and in consequence the pressure in a recently inflated tire decreases in proportion to the diffusion of the oxygen. When the tire is reinflated the proportion of nitrogen within the tire, of course, becomes larger. So long as the original air remains in the tire this proportion continues to increase with every inflation, and thus the loss of diffusion becomes gradually smaller. The temperature of the outer air is responsible only for the very slightest changes in the interior air pressure of a tire. These changes are so slight as to be negligible.

Over-inflation likewise is injurious—not to the tire so much as to the car. An over-inflated tire has little or no resiliency and thus transmits shocks to the chassis, which under incessant jarring is bound to suffer. It is obviously necessary, therefore, to keep the tires pumped up to just the right pressure. The only way to accomplish this is frequently to use a pressure tester.

Damage That a Packing May Do.

Although the idea of providing a stuffing gland at the top of the valve guide to prevent the loss of oil from around the tappet is good, care should be exercised to keep the packing from interfering with the free operation of the tappet, else a sluggish motor will result.

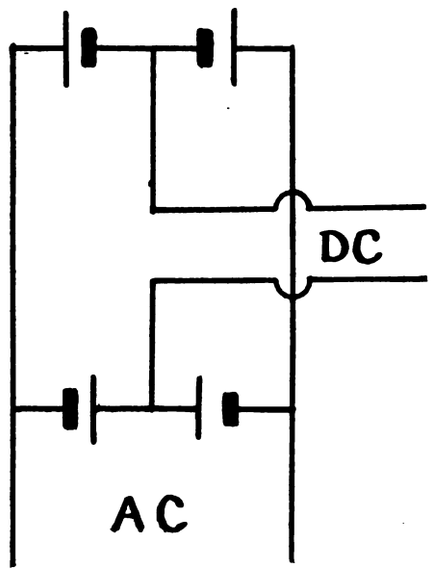
NAVALATUM NEW FORM ALUMINUM

Metal Specially Treated by British Formula Has Remarkable Properties — Anti-Friction Material, Strong and Light.

When, almost 30 years ago, aluminum ceased to be a metallurgical curiosity and its employment for practical purposes was commenced, great hopes were entertained for its ultimate use for a variety of purposes which up to that time had required heavier metals or wood construction. Unfortunately, however, the light weight of the then new metal was almost its only really valuable property. As is fairly well known, it could be cast and otherwise worked in a number of ways and soon became fairly useful. But castings were brittle and under the influence of the elements soon deteriorated and became practically worthless. Even promising alloys of the day failed after one or two years and it was not until comparatively recently that really satisfactory alloys were produced. At present such alloys are used with entire success.



The study of the metal always has been an absorbing one for metallurgists, however, and the discoveries that have been made and the new alloys which constantly are appearing, each has some particular virtue which makes it applicable to some particular purpose. Few alloys have the desirable property which will permit their use for all purposes, though within the past few weeks a new alloy has been developed abroad for which great claims are made. The new alloy is styled Navalatum, and though it is not as yet on the market, it soon will be exploited by a British company bearing the same name and having headquarters at Worcester House, Walbrook, E. C., England.

Strictly speaking, the new product is not an alloy as the word usually is understood. Instead, it is pure aluminum treated with a flux after the manner that Bessemer has made famous in his process for the conversion of iron into steel. While its texture, structure and physical properties are changed in the process, its lightness is not impaired; it is said that in some cases the specific gravity even falls slightly. In castings, it is said by the manufacturers, Navalatum has a greater strength than the best gun metal combined with the ductility of malleable iron; furthermore, in its drawn or rolled condition, it is possessed of strength very nearly equal to that of mild steel and has the annealing properties of copper. Among the other broad claims made for the new product are that it is not corroded by salt water or dilute acids and that it does not tarnish in the atmosphere.

Navalatum is said to cast the same as ordinary aluminum, brass or gun metal, no special furnace or other apparatus being necessary, and the castings having perfectly clean edges in the fine lines of the moulds. The breaking strain is from 32,000 pounds upward and the specific gracity is 2.6. Another of the peculiar properties of the metal is that it can be drawn cold either as bars, angles, tubes or wire, as readily as brass or copper, without the necessity for special apparatus, and can be annealed in exactly the same manner. Furthermore, it can be soldered and welded, and by reason of the fact that screws and rivets may be made of it, and two parts of the same material thus fastened together without the necessity for the use of any other metal, electrolytic action may be positively eliminated. As a last and clinching argument in favor of the new product, it is said to be an excellent anti-friction metal.

To Increase Efficiency of Rectifiers.

Probably the chief reason why the chemical rectifier is not in more common use for charging storage batteries where alternating current only is obtainable, is the

very low efficiency of the apparatus when connected in the ordinary manner. Theoretically the best that can be obtained from this type of rectifier when connected in series with the battery is about 50 per cent., as the aluminum cells act as a "check valve" and prevent the return of one impulse which consequently is lost. If, however, the cells are connected as shown in the accompanying diagram, the efficiency is considerably increased and the only losses are those which result from the resistance of the electrolyte and which are dissipated as heat.

Why New Fans Should be Watched.

The blades of some fans have an objectionable habit of working loose on account of defective riveting at the hubs, and for this reason a new fan should be rather carefully watched for a time. A loose blade can do a good deal of damage, and when one blade goes the rest of the fan often is damaged, if running at very high speed, because of the lack of balance.

FARRIERS STILL FIND MANY HOOFS

Business so Good Horseshoers Consider a Raise in Rate Advisable—Trade Authority Tells the Reason.

Despite the fact that the motor driven vehicle has made inroads upon the domain of the horse, its inroads have not greatly disconcerted the horseshoers, at any rate, according to J. C. Buckley, of Detroit, editor of the Horseshoer's Journal. Buckley says business is as good as ever, so good, in fact, that because of the increased cost of supplies the Detroit master horseshoers consider it advisable to raise their rates, and so far as the number of horses in use is concerned, Detroit is not greatly different from the average growing American city.

"The growing trend toward motor trucks," said Mr. Buckley, "and the increased use of automobiles has positively not hurt the horseshoers, no matter what one may think. In fact, the master horseshoers, after a careful canvass, have decided that business is as good, if not better, that at any time the oldest horseshoer can recall.

"They admit that in the shoeing of carriage and driving horses a marked reduction of work is seen. Indeed, the volume of light driving or carriage horseshoeing that is done is of comparatively little consequence.

"But the great growth in the city's population has more than made up for this loss of the light work by the great increase seen in the number of delivery and draft horses on which horseshoers are kept busy. The only complaint heard among the followers of the trade is toward the reduced profits in the business. The heavier grade of work to be done calls for more expense in buying supplies than formerly, and besides, the cost of all supplies has increased.

"So, too, have wages of workingmen increased, and with the cost of living almost prohibitive it has been decided by the horseshoers to ask an increased price for shoeing. The horseshoers in other cities are paid from 25 to 50 per cent. more than Detroit shoers are now getting, they say."

Provides an Arm Rest in Rear Seat.

By way of increasing the comfort of passengers who occupy tonneau seats, the manufacturers of Argyle cars, which are made in Scotland, recently have developed a clever device in the form of a removable arm rest for attachment in the center of the seat. It is pointed out that the comfort of motorists may be greatly increased, providing a rest for both arms is available, and it is hoped that the new device will have the desired effect. Of course, it cannot be used when the rear seat is occupied by more than two persons, for which reason it is so constructed as to be readily removable and may be stored beneath the seats.

GOOD SERVICE SECURED FROM DOUBTFUL EQUIPMENT

How One of the Large Express Companies Converted Battery-Driven and Even Horse-Drawn Vehicles Into "Batteryless" Trucks—Lessons That Were Learned by the Change and the Manner in which the Reconstruction Affected the Efficiency of the Service.

It not infrequently happens that battery driven trucks are put to service that is too severe or too extended for the capacity of the batteries, the result being that the supply of current becomes exhausted before the day's work is completed, with no means of either charging batteries or obtaining a "boost." While troubles such as these are far more infrequent than was the case a few years ago, due not only to the greatly increased number of charging stations that are available for boosting purposes, but also to the superiority of the present-day battery over its predecessors, there still are not a few electrics engaged in commercial work that do not quite come up to the mark because of some drawback that is more or less directly traceable to the unavoidable limitation of the current supply when on the road.

Another difficulty that sometimes occurs in connection with electric commercial vehicles is that through improper handling the batteries become worn out or so seriously damaged as to be practically useless, leaving the car in a state of enforced idleness until a new source of energy is installed. A new battery costs a good deal of money, however, and there are many instances where owners of such machines, having neither the facilities nor the men to care for batteries that are used in severe service, prefer to let the machines stand idle, or else sell them for a song, to purchasing new batteries with the expectation that they will shortly go the way of the first sets of cells. It perhaps is unnecessary to add that these are not imaginary combinations of circumstances, but that they actually exist to a considerable extent.

Individual owners of one or two vehicles usually "scrapped" their machines or sold them for what they would bring and placed the unrecoverable cash in the every ready profit and loss column. The big concerns are even more averse to that proceeding than are the "little fellows," however, and at least one, the United States Express Co., made a determined effort to make use of the old equipment by the ingenious expedient of discarding the batteries altogether and installing in their stead, and in their place in the cars, generating plants, each consisting of a small gasolene motor direct connected to a direct current generator, the capacity of the outfit being sufficient for all the ordinary requirements of the work done by the vehicles. The trucks that required rejuvenating at the nerve-centers, so to speak, were of various sorts and sizes, and at least one was an impossibility as a battery-driven machine, because its great weight, its comparatively small carrying capacity and its notable extravagance in the matter of current consumption precluded its use in any ordinary work, though, on the other hand, it was strong and eminently reliable while it was working.

The experiments that were made began with the installation of an engine and generator directly on the battery bed; the old controller was used and the current from the generator was carried to it just as was the current from the battery, and thence went to the motor or motors, as the case might be. Later more elaborate and more powerful installations were made. In running these converted machines several facts were impressed upon the experimenters—facts that, though quite familiar to users of machines of the gas-electric type, were rather novel to both battery men and gasolene men. In the first place, it was very noticeable that the machines could be driven at a much higher speed on level roads with the gasolene generating plants than with the batteries; this is accounted for by the fact that it was possible to run the voltage up to a point far above that of the batteries, and as the speed of a motor depends upon the voltage, it was not surprising that the cars sped along the levels at speeds that were quite remarkable. Incidentally, it speaks well for the motor construction in general and for the insulation in particular that, while they all were built for voltage not to exceed 90, they withstood without indications of weakness pressures up to 150 and even 175 volts.

Another fact, considerably less gratifying, was that when it came to applying maximum power for a short, slow pull the generating plant was found inferior to the battery—that is, the battery was capable of delivering a tremendous amperage for a very short time, while the generating plant was limited, of course, by the maximum horsepower of the engine. This was a matter of comparatively small moment, however, for though the engines first used were too small for use under unfavorable conditions, the use of a little more horsepower afforded a satisfactory remedy, though it may be said that the installation of an engine capable of developing a maximum output equal to the maximum output of a battery suitable for the same car would involve sizes and weights of unjustifiable magnitude, and really was unnecessary.

The first installations of gasolene-electric generating plants as substitutes for batteries were made with two-cylinder opposed engines, air-cooled, of high speed because it was considered necessary to use a high-speed generator in order to keep the weight within reasonable limits. Incidentally, there was a saving in weight over the battery installation of approximately a thousand pounds. Unfortunately, the first engines selected were faulty in that they failed to deliver their rated horsepower, they failed to cool when worked hard, and they failed to lubricate adequately; in other words, they came near to being thorough failures. They served their purpose, however, in that they demonstrated the feasibility of the principle involved, and as a result larger motors—water cooled, however—were employed.

By special designing it was found possible to have built generators that, while light in weight and small in size, were capable of delivering heavy currents and withstanding high overloads for short periods, but which, nevertheless, ran at very moderate speeds. For instance, the smallest generator delivered its normal output, 28 amperes at 90 volts, at 600 R.P.M., and had an overload capacity of 200 per cent. for ten or fifteen minutes. Its weight was 279 pounds. A larger size, weighing 450 pounds, delivered its normal current of 84 amperes at 90 volts at 575 R.P.M. and had the same overload capacity. This low speed made it unnecessary to use fast-running motors, and also had the advantage that sufficient current to start the car was generated without the necessity for speeding the engine up to a high rate.

The first motors used, rated at 15-18 horsepower, never would do much better than 10 horsepower; nevertheless, they handled loads of from one to nearly three tons. Naturally, the heavier loads could not be carried up very steep grades or be properly taken care of under difficult conditions; but loads of one ton and less were handled with surprising facility, even on fairly steep hills, and though the maximum available power was very considerably less than with a battery, the average time made was much better. This is accounted for by the fact that the speed on the level was better than the speed possible with battery current and more than made up for the time lost on the hills.

In most of the vehicles experimented with there were two driving electric motors, and this greatly facilitated control, for the connections made through the controller

Digitized by Google

permitted the motors to work in series for heavy pulling and in series-parallel for speed. In the first machines, with low-powered engines, the series grouping was considerably in demand, just as is the low gear of a gasolene car with a small motor. When the power was increased, however, the series notch was used only under severe conditions, and practically all running was done on series-parallel.

The cars handled with a flexibility comparable to that of a steam car. With the engine running at its lowest practicable speed it turned over the generator so slowly that only a feeble current was generated—nothing like enough to move the car. As the R.P.M. rate increased, however, the current output increased proportionately. Therefore the driver, in starting the car, would first see that his controller was in the off position and then start his engine. Mounting to his seat, he would swing his controller handle to the series-parallel or full speed position, which, of course, would have no effect so far as starting the car was concerned, because of the feebleness of the current. By opening the throttle and advancing the spark. the engine was speeded up and the car started on the rising voltage with a smoothness that could not be exceeded.

If the engine was speeded up suddenly there was a slight lag in the response of the car to the impulse—or, rather, there was a cushioning effect, so that there were no shocks or jars. Of course, any speed could be held indefinitely, merely by regulating the engine speed, so that the handling of the machine was much like the handling of a "steamer." This smoothness of operation was found to be a considerable advantage with the class of drivers that the express companies find it necessary to employ. It was possible to start the machine with a sudden jump by first speeding up the engine and then throwing on the controller; but it was a little easier to handle the car in the proper way, and therefore there was very little trouble from this source except in an occasional case of forgetfulness on the part of a green driver.

As the experiments progressed, larger installations were made, and with these it was found advisable to mount the engine and generator on a separate frame which was hung under the car in the place formerly occupied by the battery. The power plant thus formed a unit, and its attachment was a comparatively simple matter, especially as it involved no extra bracing or strengthening of the car—in fact, in all cases there was a very great saving in weight over battery installations, and this was taken advantage of by increasing the normal load rating to the extent of the saving in dead weight.

The encouraging results obtained from the substitution of generating plants for batteries led to experiments in the conversion of horse wagons into automobiles by a somewhat similar process. One of the experiments consisted of replacing the front wheels of a standard "double" express wagon—that is, a two-horse wagon—with a pair of couple-gear wheels, in which the electric motors are enclosed in the steel disks which take the place of wheel spokes, and drive through gearing. Nominally the wagon carried one ton; actually it carried three and one-half tons on at least one occasion—and, in the vernacular, it got away with it. The power installation consisted at first of one of the air-cooled engines already referred to; and though several months' fairly satisfactory work was done with this outfit, the engine finally went to pieces by the broken connecting-rod route, and was replaced by a more substantial machine of the water-cooled type.

As no provision had been made in the first place for a radiator, the dashboard of the wagon was cut away and a radiator attached by means of iron clamps and bands. There was absolutely no way of running a belt or shaft for a fan, but the problem of drawing air through the radiator was solved by the ingenious expedient of mounting an ordinary office fan, with its running direction reversed, directly behind the radiator, and connecting it with the main circuit. Beyond a little oiling occasionally, the fan got no attention, and it needed none. As soon as the generator started to generate current the fan would commence to buzz, and the harder the machine worked the more air the fan handled. Thus it was largely an automatic arrangement, and though intended only as a makeshift, it never gave any trouble and always cooled adequately. The controller used was of the ordinary battery car type. As, however, the car had but two speeds, or, rather, two running positions of the controller, the other three notches of the five-speed controller were connected up to graduated resistance, so that the car could be started with the engine running at full speed and delivering full current, the effect being practically the same as when starting with battery current.

In all these gas-electric machines, whether converted horse wagons or "batteryless" electric cars, so to speak, there were field resistances installed. The field resistance consisted merely of a rheostat in the field circuit of the generator. By cutting resistance into the field circuit, the flow of current through the field coils was more or less choked and the fields thus weakened, so that they exerted less "pull" on the armature and relieved the strain. The result of cutting in resistance is the immediate dropping of the voltage and the speeding up of the engine, so that by the time the generator resistance reaches the former point the speed of the engine is considerably higher. In other words, the generator does the same work at a higher speed, and thus with more driving power from the engine. The whole effect is that of a low gear with, however, a very large number of steps.

Large machines carrying up to five tons were found to work just as well with the generating plants as did the small cars. and notwithstanding the double change in the form of energy—that is, from mechanical to electrical and back again from electrical to mechanical—the gasolene consumption was sufficiently low to make the operation of the cars less expensive than with batteries. Engines of up to 40 horsepower were installed, with generators of suitable capacity, and in some cases two-cycle motors were used with good results. Because of the lack of vertical space, all the motors used were of the horizontal type, and no trouble was experienced due to this form of construction. It was found an easy matter to train ordinarily intelligent horse drivers to handle the machines, because of the simplicity of the control system, and it was rather difficult for even a clumsy and careless driver to do much harm before his negligence was discovered.

Says Paint Does Not Affect Radiators.

Although it generally is supposed that painting a radiator has a material effect on the efficiency of the device, experiments conducted by Prof. C. L. Norton, of Boston, would tend to prove that, provided the character of the surfaces are the same, a painted radiator is, to all intents and purposes, just as efficient as one which has not been so treated. If, however, the surface is roughened after the painting operations, the efficiency of the radiator is materially increased, for the rough surface dispels the heat more readily than a glossy surface.

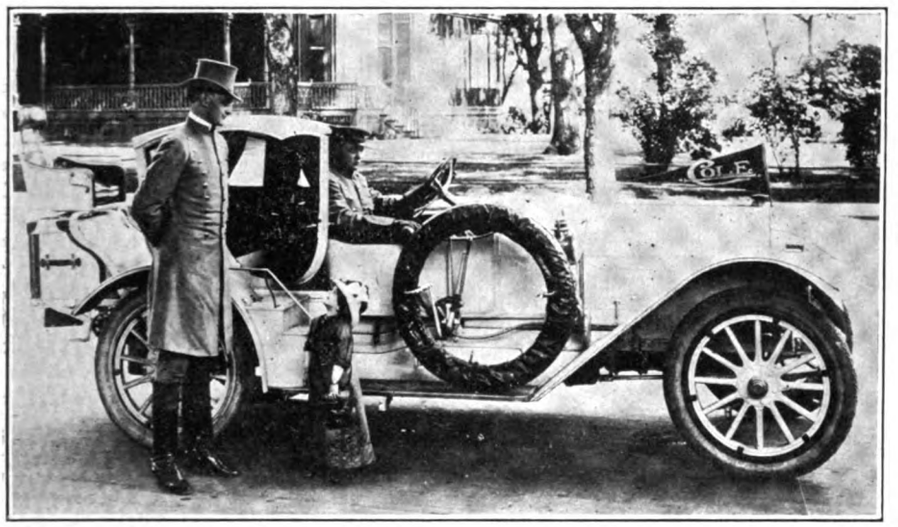
To Remove Tar Spots from Bodies.

It seldom is possible to pilot a machine over newly tarred roads without transferring at least a few splotches of the sticky composition to the body. If treated in time, the spots are not difficult of removal. The machine should be washed to eliminate all grit, and dried by patting with the chamois so that the tar will not be smeared. Vaseline or butter next should be applied over each spot and worked in with the fingers. A thorough wash with body soap and a final polish in the usual manner completes the operation.

Rain Water as a Cure for Furring.

Probably no cure for "furring" of a radiator and connections is better than the simple use of rain water. Such water naturally has no minerals dissolved in it, and consequently will dissolve those which are present in the cooling system. The water should be drained off when hot, for it is then that it holds the greatest quantities of soluble salts in suspension.

Where Soft Tires Make Easier Going.



Sandy roads, in which the wheels sink deeply, may be more easily traversed, even by very heavy cars, merely by deflating the tires about one-half, so that they spread out and form a wider traction surface; this serves to counteract the sinking effect.

LITTLEST COUPE FOR LITTLEST LADY

She's the "Miniature Melba" and Has a Cole Car Built to Fit—Requires Stairway to Enter Car.

While the commoner complaints as to the size of car bodies is that they are too small, there frequently being men who specify excess leg room and ample seating width, the Cole Motor Car Co., of Indianapolis, Ind., has encountered an extreme opposite demand and to meet it has produced what is probably the smallest coupe in actual use, at least, so far as the body is concerned. The customer, whose size was the basis of dimensions, is somewhat below the average height, although some women are almost lost anyway in the tonneaus of a few of the more luxurious models extant, but she apparently comes close to the record with 25½ inches from top to toe.

PRINCESS VICTORIA, HER GIANT FOOTMAN AND HER COLE COUPE

A stock roadster chassis of 1912 model was used, but the coupe part was of necessity entirely special in construction. The driver's seat was left intact, but the gasolene tank and trunk on the rumble deck were removed and the little enclosed body, almost a "cubby hole," was fixed in place, and, aside from dimensions, is fitted up just like an ordinary sized coupe; the upholstery is red satin. Since the diminutive owner would have some trouble making the step from the ground to the running board, there was constructed a toy folding yacht companionway, which, when not in use, folds under the running board, and to further assist the little lady in getting "upstairs" is a doll staircase on the running board.

Of course, since this arrangement is ideal for attracting attention, it fortunately happens that the little woman is an actress, known as Princess Victoria, "the miniature Melba," who is now touring the Canadian Northwest; and to further gain the publicity which is dear to the stage-worker's heart, the princess is the possessor of a footman, and he is some footman. He is a giant anyway, being seven feet tall, but when he stands by the opened door while the princess enters, the contrast in size is startling and his height is further accentuated when he mounts to a footman's seat attached at the back of the coupe body. The finish is in white enamel. Princess Victoria is 23 years old and weighs 193¼ pounds, and when the outfit was first seen by a friend he asked why she did not be more economical and have an extra large pocket made in the footman's coat and ride that way.

Dictaphones to Convict "Cutout Fiends."

That the dictaphone, which recently has become the one "best bet" on the witness stand, will be given its innings testifying against recreant motorists who are prone to use the muffler cutout in localities where such practice is looked upon with disfavor, seems evident from the case which was tried in an East Boston (Mass.) court last week. The defendants were owners of motor-equipped fishing boats who failed to muffle the motors sufficiently to make the exhaust inaudible at 2800 feet, at which distance the dictaphone made records which subsequently were heard by the Court, who, however, released the prisoners with a warning. It seems not at all unlikely that "noise traps" which will be in point of productiveness equal to the ever popular speed trap, will be established in localities where cutout ordinances are in force.

French Subsidy Trials Now in Progress.

The annual trials which the French government holds each summer to determine the fitness of competing vehicles for the use of the army in case of war, the manufacturers and owners of the vehicles that pass the tests being awarded a government subsidy, were inaugurated last week. No less than 68 trucks are taking part in the trials, which will last for several weeks.

ACETYLENE AS VIEWED IN ENGLAND

Laws that Make its Use in Compressed Form Illegal—British Engineer Explains Lack of Engine Starters.

Throwing interesting light on the engine starting problem as it is viewed in England, where, though devices of the kind have not as yet attained to anything like the popularity they enjoy on American soil, the problem nevertheless is spelled with a capital P and hedged about with much that is mysterious—to British intellectualities. C. A. Branston, who is a British engineer, in attempting to explain the lack of acetylene engine starters abroad, points out that as the law stands at present their use is illegal. Furthermore, in his opinion, the lawmakers have been perfectly right in thus placing a ban on the use of "compressed acetylene."

Woeful lack of experience can be the only excuse offered for a later statement, in which he says that "though the Home Secretary has the power to make an exception, it is sincerely to be hoped that he will do nothing of the sort, as in the high-pressure type of self-starter a quantity of acetylene is used at a pressure far beyond that of two atmospheres, at which the gas becomes explosive, while in the low-pressure type, dangerous mixtures of acetylene and air are employed, compressed to a considerable extent by hand, and here the possibility of the firing back of this mixture must be difficult to prevent."

Thus though the eminent engineer's views are at variance with those that are held in America, the fact remains that the use of acetylene engine starters in England really is illegal, though several manufacturers equip their cars with them—incidentally, they are of American make—and as yet no accidental explosions have been recorded nor have the police authorities exercised their prerogative to prohibit their use. In consequence of these facts, and particularly in view of American experience with compressed acetylene, Branston's views, which were published in the Automobile Engineer, would seem to be hypothetical. In arriving at his conclusions, however, he reviews briefly the facts which have prompted British authorities to overlook the use of compressed acetylene, when stored in steel cylinders, and his dissertation is interesting if for no other reason than that it tends to show how thorough(?) was the investigation upon which the British laws are based.

"When the use of acetylene gas acquired a sudden popularity as a result of the independent and simultaneous discoveries, in 1892, of Moissan and Willson concerning the commercial manufacture of calcium carbide," he says, "the Home Office (with a cautiousness for which one may perhaps doubt the necessity) in February, 1897,

Digitized by Google

brought this, in itself, harmless substance (calcium carbide) within the provisions of the Petroleum Act, 1871, which probably has done not a little towards impeding the extension of the use of acetylene for illuminating and other purposes.

"Most of us will remember the numerous serious accidents in the shape of explosions which occurred during the middle nineties, chiefly in France, and which were due, to some extent, to the ignorance of the generator manufacturers of the principles involved in the safe generation of this gas. But in the majority of cases the cause was traceable to the unwarrantable ignorance and gross carelessness of those in charge of the apparatus, an ignorance and carelessness which, at the present time, seems to find its scope in causing the lamentable accidents due to the use of petrol, which are so frequently reported. It was only natural, therefore, that when the properties of this gas had been thoroughly investigated, restrictions should be placed upon its manufacture and use under certain circumstances. Thus an Order in Council of November, 1897, limits the pressure under which it may be stored or used to 100 inches of water (3.6 lb. per sq. in.) in view of the fact that at a pressure of 30 lb. the gas becomes explosive. Acetylene above this pressure is placed within the provisions of the Explosives Act, 1875.

"With a view to improving the illuminating qualities of oil gas for train lighting purposes, Gerdes and others conducted numerous experiments in Germany to find a mixture of acetylene and oil gas which could safely stand compression, and in March, 1898, the Home office authorized the use of a mixture of 20 per cent. acetylene with oil gas at a pressure not exceeding 150 lbs. per sq. in. The facility with which acetylene is liquefiable (at a pressure of 21.5 atm. at 0° C.) seemed to promise a convenient way of storing the gas in bulk, but its unfortunate property of explosibility soon put an end to this. Our knowledge of the properties of compressed, liquid and dissolved acetylene is due chiefly to the exhaustive researches of Berthelot and Vieille. Acetylene when compressed beyond two atmospheres becomes explosive—i. e., it is liable to detonate without the presence of air. Berthelot and Vicille, however, found that to cause it to detonate either through shock or, to a lesser extent, the external application of heat, was a far from easy matter and one not likely to occur in practice, though the possibility of the occurrence was, of course, sufficient to prohibit its use. In 1897 Claude and Hess had observed that one volume of acetone at 15° C. and at atmospheric pressure dissolves 25 volumes of acetylene, while at a pressure of 12 atmospheres this rises to 300 volumes. A rise in temperature, however, causes a rapid decrease in the solubility in acetone which only amounts to one-half of the above figures at 50° C.

"Berthelot and Vieille made numerous experiments with solutions of acetylene in acetone and found that at a pressure of about 10 atmospheres no explosion can take place in the heart of liquid itself; also the pressure of an explosion (caused, e. g., by the detonation of the free gas standing above the liquid) is but one-tenth of that which corresponds to the spontaneous dissociation of all the acetylene present. If, however, the pressure be raised to 20 atmospheres or more, the explosive pressure rises nearly to the same height as that due to an explosion of liquid acetylene. It should be mentioned that the pressure of explosion also varies according as to whether the detonation is produced in the liquid itself or in the gas above it. The difference just mentioned is due to the fact that in the first case the acetone is destroyed at the expense of, and by, the heat of the burning acetylene, and therefore absorbs part of the heat due to the explosion of the latter; in the second case the acetone is decomposed by the shock of the explosion, and this decomposition causes a large increase in volume, or in pressure if at constant volume.

"Storing acetylene dissolved in acetone in steel cylinders is impracticable and dangerous, as the liquid contracts as it releases the gas, so that a space is left in the container, filled with gas at a dangerous pressure. This difficulty has been ingeniously overcome by filling the container with a porous substance such as kieselguhr, into the minute interstices of which the acetone with the acetylene in solution is forced, or even the acetylene by itself without a solvent. The principle upon which the safety of this method of storage rests is that the acetylene or its solvent is contained in cells, the dimensions of which are below those which will permit the propagation of the explosive wave.

"In accordance with these results, the Home Office has permitted the use of acetylene, either compressed or dissolved in acetone, when stored in steel cylinders which are completely filled with porus matter, the pressure not to exceed 150 lb. per sq. in. (Order in Council, April, 1901.) In connection with dissolved acetylene, it may be interesting to mention incidentally that, according to Wolff and Caro, the upper explosive limit of acetylene is reduced by 16 per cent. when acetone is the solvent used, owing to the presence of some of the solvent held in suspension by the gas on leaving the container. The wide explosive range of acetylene-air mixtures (2.5—80 per cent. according to Gerdes; 2.9—64 per cent. according to Le Chatelier) is the reason why the Home Office has prohibited all mixtures of acetylene and air, whatever their proportions or pressure (July, 1900) the mixing which occurs in the burner itself and the air unavoidably introduced into a generator in charging, being necessary exceptions, of course. From the preceding it is clear that, as the law stands at present, the use of acetylene self-starters is illegal. Though the Home Secretary has the power to make an exception, as in the cases mentioned above, it is sincerely to be hoped that he will do nothing of the sort, as in the high pressure type of self-starter a quantity of acetylene is used at a pressure far beyond that of 2 atmospheres at which the gas becomes explosive, while in the low pressure types dangerous mixtures of acetylene and air are employed, compressed to a considerable extent by hand, and here the possibility of the firing back of this mixture must be difficult to prevent."

Cheaper Rubber is Predicted Abroad.

That the price of rubber is due to take a tumble in the near future appears to be an opinion that prevails abroad in several apparently well-informed quarters. Nor are these opinions based upon the possibility of the early realization of sundry dreams of the production of synthetic rubber at ridiculously low cost. It is pointed out by more than one of those who have expressed their views, that at the time rubber "plungers" were more than numerous, and as one of the results of the activities immense tracts of land were planted to rubber in the expectation of immense profits accruing. But, as every one knows, rubber trees require a long term of years in the soil before they become of commercial value. And in the year 1914, according to the views of the experts, the trees will have reached to the state of maturity where the production of rubber will be almost immeasurably increased. Hence the optimistic views and the oft-reiterated prediction that in all probability rubber soon will be standardized in the vicinity of 75 cents a pound. At present, up-river fine Para is listed at $1.15, around which figure it has hovered since the first of the year. Whether or not the predictions will come true remains to be seen, but in the meantime, in expectation of their fulfilment, it is said that the Road Board and the Local Government Board in Great Britain both are holding off from promulgating new laws regarding the use of rubber and steel tired vehicles until the price of raw material reaches a lower level.

Removing Dents from Metal Bodies.

The removal of a dent from the aluminum or sheet steel body of a motor car is a "pretty" job for the experienced body painter. The surface of the metal is first cleaned, then touched up with metallic paint so that the putty which next is applied to fill the cavity will get a "bite." After the putty has set, the whole is rubbed down with sandpaper and painted or finished off with varnish.

With the steel sheet panel, however, trouble sometimes is caused by the formation of rust which, if it has not penetrated too deeply, can be removed with a wire brush and sandpaper. The surface should then be given a coat of anti-rust paint and the putty applied and the job finished in the usual manner. Where the rust has penetrated too deeply for removal with the brush and sandpaper the sand blast must needs be resorted to.

1,011,431. Motor Driven Vehicle. John B. Heverling, St. Louis, Mo. Filed Mar. 23, 1910. Serial No. 551,136.

1. In a motor driven vehicle, a driving axle, a friction wheel carried thereby, a vertically moving motor driven friction wheel adapted to engage the surface of the first mentioned friction wheel, and means for simultaneously elevating the motor driven friction wheel, and tightening the band brake on the first mentioned friction wheel.

1,011,471. Pneumatic Tire. William A. McCool, Beaver Falls, Pa., assignor to Hercules Tire & Rubber Company, a Corporation of Delaware. Filed Dec. 11, 1909, Serial No. 432,580. Renewed Apr. 11, 1911. Serial No. 620,460.

1. A pneumatic tire, consisting of a plurality of layers of elastic material and composed largely of rubber, and which tire is thickly studded throughout its body portion, including the parts thereof which come near the rim of the wheel, with pegs passing through said layers and strongly securing the same together.

1,011,480. Internal Combustion Engine. Alden E. Osborn, New York, N. Y. Filed Mar. 11, 1910. Serial No. 548,748.

1. An internal combustion engine comprising a working cylinder provided with an extension in line therewith at its upper end constituting a main valve chamber and having an annular valve chamber surrounding the same, and a distributing passage connecting them, a main valve mounted within the first said chamber for controlling the inner end of the said distributing passage, an annular valve mounted in the second said valve chamber for controlling the outer end of the said distributing passage, and means for operating the valves.

1,011,520. Combined Internal Combustion and Fluid Pressure Engine. Harry Benwell Stocks, Manchester, England. Filed Nov. 25, 1910. Serial No. 594,193.

1. In combination, an internal combustion engine, a steam generator into which water heated by the cylinders of the internal combustion engine is pumped, a compressor to force exhaust gases from the engine into the steam generator, and a steam cylinder in which steam from the steam generator is used, substantially as described.

1,011,560. Shock Absorbing Mechanism. Adolph J. P. Bertschy, Chicago, Ill. Filed May 20, 1908. Serial No. 433,799.

1. In a vehicle, a frame, axles supporting said frame, a set of upper cushioning devices, a set of lower cushioning devices, said sets of cushioning devices being adapted to use a fluid cushioning between said frame and said axles, means for exerting pressure on the cushioning medium by the vibrations between said frame and said axles, means for automatically supplying the cushioning devices with the medium thus placed under pressure, a dash board for said vehicle, means on said dash board for controlling the upper set of cushioning devices either independently or collectively, means on said dash board for regulating the lower set of cushioning devices either independently or collectively, and means on said dash board for simultaneously controlling all the cushioning devices.

1,011,591. Driving and Steering Mechanism for Motor Vehicles. William Henry Douglas, Belleville, N. J., assignor to Healey & Co., New York, N. Y. Filed June 21, 1910. Serial No. 568,142.

1. A motor vehicle provided with a driving and steering wheel having a hub and a rim, a driving axle, a universal joint connecting the driving axle with the hub, a steering knuckle intermediate the hub and rim, the said steering knuckle being approximately ring shaped and formed in sections, means for securing the sections of the knuckle together, the said sections each having an annular inwardly extending flange, approximately at the center thereof, ball bearings interposed between the said flanges of the sections of the knuckle and the outer side of the hub, and a supporting member having arms provided with trunnions engaging said knuckle at the top and bottom thereof.

1,011,638. Spring Wheel. William Morris, Cleveland, Ohio. Filed Nov. 14, 1906. Serial No. 343,332.

1. The combination of a hub, telescoping spokes carried thereby, trunnions carried by said spokes, wheels on said trunnions, and a tread portion having inner peripheries on which said wheels ride.

1,011,641. Carburetter. John Anderson Paterson, Wellington, New Zealand. Filed May 19, 1909. Serial No. 497,075.

1. In a carburetter for internal combustion engines, the combination with a chamber through which the exhaust from the engine is passed, of a carburetting member located within such chamber, means for conducting air to the carburetter, and means for conducting air for attenuating the generated mixture of vapor and air, both said air conducting means being adapted to be heated by the gases in said exhaust chamber.

1,011,679. Resilient Wheel. John Vollman, Racine, Wis., assignor of one-third to Peter De Vogel, Racine, Wis. Filed Dec. 3, 1910. Serial No. 595,455.

1. In a resilient wheel, an inner channeled rim with its flanges extending outwardly, an outer rim spaced from said inner rim and composed of a plurality of segmental sections hingedly connected at their ends, one end of each section having apertured outer lugs at the side edges thereof and the other end having similar inner lugs spaced from the side edges and from each other, said last mentioned lugs being adapted to be arranged between the outer lugs of the adjacent sections, bolts connecting the lugs of said sections, plate springs having cylindrical lugs on one face at one end thereof arranged between said inner lugs and engaged by said bolts, the said springs having flanges extending beyond the opposite ends of the lugs thereof and adapted to overlap and bear on the lugs of the tire sections, and means for connecting the free ends of said springs to the inner rim.

1,011,696. Carburetter. Alexander Winton, Cleveland, Ohio. Filed May 12, 1911. Serial No. 626,795.

1. In a carburetter, the combination of a main carburetting chamber, an auxiliary carburetting passage having its two ends communicating with the ends of the main carburetting chamber, a gasolene supply for the auxiliary passage, a gasolene supply located in the main carburetting chamber at a point between the ends of said auxiliary carburetting passage, and throttles in the main carburetting chamber controlling the passage of the mixture through the main carburetting chamber and the auxiliary carburetting passage.

1,011,834. Friction Clutch. Harry W. Nichoalds, Detroit, Mich., assignor to John B. Whelan, Detroit, Mich. Filed Oct. 10, 1910. Serial No. 586,185.

1. In a friction clutch in combination with a driving shaft a casing fixed thereto and provided with a cavity having oppositely inclined friction faces, a plurality of radially arranged friction members adapted when expanded to engage said friction faces, wedge members adapted to engage therebetween, whereby said friction members may be forced centrifugally, resilient means for normally holding said wedge members in expanding position with reference to said friction members, and means for releasing said wedge members and thereby said frictional members from such position, thereby terminating the frictional engagement, substantially as described.

1,011,860. Electric Tire-Vulcanizer. Frederick F. Schwentker, Schenectady, N. Y., assignor to General Electric Company, a Corporation of New York. Filed Apr. 17, 1906. Serial No. 312,119.

1. An electric tire vulcanizer comprising a metallic body portion of relatively hard metal, an electric heating unit secured thereto, and a mass of softer metal molded to the body in the shape of a tire and in heat conductive relation with said unit.

1,011,875. Internal Combustion Engine. Charles A. Sullivan, Windsor, Ontario, Canada, and James W. Potter, Detroit, Mich., assignors of one-fourth to Edward J. Woodison and one-fourth to Charles L. Ackerson, Detroit, Mich. Filed Mar. 4, 1910. Serial No. 547,191.

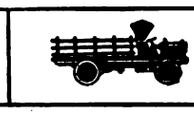
1. An internal combustion engine, having in combination a fixed cylinder, a piston, a member intermediate said cylinder and piston, arranged to act as a piston with respect to said fixed cylinder, and as a cylinder with respect to said first-mentioned piston, a crank shaft, pitman connections between said crank shaft and intermediate member and piston adapted to cause the same to alternately approach and separate, said fixed cylinder having a fuel inlet port uncovered by said intermediate member near the limit of its outward stroke, a by-pass in said fixed cylinder having an opening into the clearance space thereof, and another opening adapted to register with the clearance space of the intermediate member when the intermediate member is reaching the limit of its compression stroke in the fixed cylinder, said by-pass adapted to transfer fuel through the chamber of the fixed cylinder to the chamber of the intermediate member, said intermediate member also provided with a port leading from its clearance space, and adapted to register with said last-mentioned opening of said by-pass, thereby establishing communication therethrough between said fixed cylinder and intermediate member, and a firing plug introduced through the walls of the fixed cylinder, with which the said port of the intermediate member is adapted to register when the piston and intermediate member are near their closest condition of approach, substantially as described.

1,011,892. Wind Guard for Vehicles. Martin L. Williams, South Bend, Ind. Original application filed Feb. 11, 1908, Serial No. 415,276. Divided and this application filed Nov. 21, 1908. Serial No. 463,738.

Digitized by Google

1. A windguard for vehicles comprising an upright lower sash, supporting brackets connected with the upper portions of the sash at each side and extending laterally therefrom, an upper sash, links connecting the sides of the upper sash with said supporting brackets at points remote from the lower sash, means for locking said upper sash either in alinement with the lower sash, or in tilted relation to the lower sash with its lower edge offset and spaced away from the upper edge of said lower sash, and means for supporting the lower end of said upper sash when lowered into position alongside of, and approximately parallel with the lower sash.

1,011,894. Tire. William H. Reed, Hartford, Conn., assignor to Revere Rubber Company, Providence, R. I., a Corporation of Rhode Island. Filed May 14, 1910. Serial No. 561,289.



1. In a wheel tire the combination with the felly and a bevel edged metallic band secured thereto, of a series of bevel edged base plates adapted for arrangement end to end on said band, clamps adapted to engage the bevel edges of said band and base plates, means for moving said clamps to firmly secure said base plates to said band, and a tread block permanently secured to each base plate.

1,011,931. Force Feed Carburetter. Charles W. Farquharson, Chicago, Ill. Filed Oct. 13, 1910, Serial No. 586,924. Renewed Nov. 8, 1911. Serial No. 659,247.

1. A force feed carburetter comprising a charge supply tube a carburetter casing arranged thereon and connected thereto, an oil conducting pipe extending through said casing and having inlet and discharge valves, a reciprocating member alined with said oil pipe, a pipe for admitting fluid pressure to said member, a hollow flexible connection between said pipe and said member, a hollow flexible connection between said member and the oil conducting pipe, a

fixed support for said member between the flexible connections, a flange on said member, and a sleeve adjustably mounted in said support in the path of the flange.

1,011,940. Rain and Wind Shield for Automobiles. Anna K. Gilson, Quechee, Vt. Filed Aug. 15, 1911. Serial No. 644,219.

A shield for vehicles comprising a flexible frame, a flexible transparent medium supported by said frame having an opening of limited area, a flexible closure hinged to swing to and from said opening, and a supporting arm hinged at one end to the flexible frame having means at its other end for connection with the closure, and movable to and from a position parallel with the frame side to which it is pivoted.

1,011,977. Ignition Apparatus for Hydrocarbon Engines. Allen Loomis, Detroit, Mich., assignor, by mesne assignments, to Packard Motor Car Company, Detroit, Mich., a Corporation of Michigan. Filed Dec. 27, 1907. Serial No. 408,231.

1. In an ignition system for hydrocarbon engines for motor vehicles, the combination with a plurality of engine cylinders, of a spark plug on each cylinder, a plurality of separate insulated conductors, a tube containing said conductors passing in proximity to said spark plugs and having an opening opposite each plug, a holder secured to said tube at each of said openings, a terminal member within each holder making electrical contact with one of the conductors, and pivoted switch arms supported by said holders in position to make contact with the spark plugs thereby making electrical connection between the terminals and plugs.

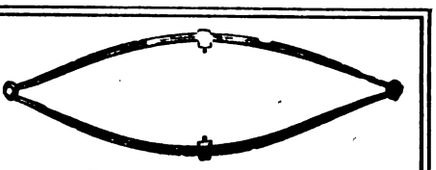
1,011,987. Wheel. Irving D. Minor and Frank A. Minor, Aurelia, Iowa. Filed Jan. 24, 1911. Serial No. 604,452.

1. In a wheel, a disk adapted to be connected to an axle and provided with an outwardly directed annular recess, an inner rim concentric to the disk and provided with an inwardly directed annular recess, a tire formed in two annular portions with lateral flanges engaging face to face and fitting respectively in said annular recesses, said flanges each having a plurality of open slots, clamp devices extending through the disk and through the slots in one pair of said flanges, and clamp devices extending through the inner rim and likewise through the slots of the other pair of said flanges.

1,012,033. Spring Wheel. Paulus Franciskus van Keep, Breda, Netherlands, assignor to The Firm of Amsterdamsche Maatschappij tot Exploitatie van Uitvindingen, Amsterdam, Netherlands. Filed June 3, 1908. Serial No. 436,452.

1. In a spring wheel, the combination with a felly and a hub, of a spring spoke having a spiral end connected to the felly and a leaf spring end connected to the hub, and abutments on the hub between the points of connection of said spokes with the felly and hub and on opposite sides of the spokes and independent of the end connections to produce flexure of the leaf spring portion upon relative rotation of the hub and felly in either direction.

1,012,115. Rotary Explosive Engine. Frederick Uhtbrock, New York, N. Y. Filed Sept. 25, 1908. Serial No. 454,817.



1. In a rotary explosive engine, a stator formed by a circular disk with a cylindrical rim; an annularly grooved rotor circumferentially surrounding said stator and rotatably mounted on the rim of the latter and forming a circular chamber with the same; three hollow pistons integral with or fastened to said rotor and dividing the circular chamber formed by the rotor and the stator into three chambers; partitions carried by the rotor and the pistons and located in the plane of the circular disk of the stator and running parallel to the sides of the rotor and dividing the chambers formed by the stator, the rotor and the pistons into compression and explosion chambers; inlet and outlet valves located in the pistons, the inlet valves facing the compression chambers, and the outlet valves facing the explosion chambers; radially reciprocatable abutments provided with rollers and having cuts into which fit the before-mentioned partitions; four lugs integral with or fastened to the stator, forming frames for said abutments; valved feed-ports situated one on either side of the frames of the abutments and leading into the compression chambers; valved exhaust-ports situated one on either side of the frames of the abutments and communicating with the explosion-chambers; guides carried by the rotor and adapted to guide the abutments into the compression and explosion chambers and out of the way of the pistons by means of the rollers fastened to the abutments; means to open the outlet valves of the pistons at and for a predetermined time; means to ignite the charges in the explosion chambers at the proper time; and means to open or to close the feed and exhaust valves and means to set in position the means that operate the outlet valves of the pistons; means of supply leading to the feed-ports and means to conduct the exhaust away from the exhaust ports; all substantially as described.

1,012,116. Cranking Device for Gas Engines. William Van Scoter, Buffalo, N. Y., assignor of one-fourth to William J. Hayes, Buffalo, N. Y. Filed Feb. 13, 1911. Serial No. 608,274.

1. A cranking device for gas engines comprising a starting shaft adapted to be connected with the engine shaft and provided with a laterally projecting coupling pin, a crank mounted loosely on the starting shaft and provided with a sloping driving shoulder adapted to engage with said pin, and a spring operating to move said crank axially and hold said shoulder yieldingly in engagement with said pin.

1,012,127. Shock Absorber. Thomas G. Cushman, Sunland, Cal. Filed May 23, 1911. Serial No. 628,903.

1. In combination with a vehicle having an axle and a frame spring supported thereon, a link pivoted at one end to the frame and extending diagonally downwardly toward the axle, another link pivoted to the axle and extending diagonally upwardly and toward the free end of the first mentioned link, and a resilient member connected to the adjacent ends of the links and connected to the frame.

GUARANTEED AUTOMOBILE SPRINGS

Our plant is devoted exclusively to the manufacture of high quality springs. All work is oil tempered and warranted. Our circulars contain valuable information. Write.

A trouble saver for the motorcyclists

This book contains more practical advice for the rider, more good hard sense, more suggestions as to how to keep out of trouble, and how to get out of it, than has ever been printed heretofore in any one book.

¶ It fits the coat pocket and it includes free engine clutches, two-speed gears, mechanical lubricators and magnetos, together with special matter on motors, valves, carbureters, fuel and important general subjects, all plentifully illustrated.

¶ Dealers and jobbers in all parts of the country are selling "Care and Repair of Motorcycles" to both new riders and veterans as the best aid in correcting and avoiding motorcycle trouble.

Sent Postpaid on Receipt of 25 Cents

Special Rates to Jobbers and Dealers on Quantity Orders.

For Sale—Wants—Exchange

15 cents per line of six words, cash with order. — In capitals, 25 cents per line —

A market place where Dealers, Jobbers and Manufacturers may buy, sell or trade used cars, parts and appliances and where help or situations may be secured at a nominal cost.

WANTED—Electric automobile repairman and a charger, two years' experience, give reference. DAVIS BROS. ELECTRIC GARAGE, 921 E. 14th Ave., Denver, Colo.

FOR SALE—Touring car, 5-passenger, in excellent condition; price reasonable. Address P. O. Box 367, Springfield, Mass.

BAKER ELECTRIC STANHOPE, just overhauled and painted, $390; will demonstrate. Victoria, $720; Newport Phaeton, $350. Telephone, Columbus 2830. BAKER VEHICLE COMPANY, 1798 Broadway, N. Y. City.

COLUMBIA, 1910, 5-passenger, 45 H. P.; fully equipped; Prest-O-Lite tank; runs and looks like new; three new guaranteed tires; cost $2,750; will sacrifice for $800. BUGGE, 571 Main St., East Orange, N. J. 'Phone 18.

FORD OWNERS, improve the appearance of your Fore Door Touring Car or Torpedo Runabout 50% for $3.25. Send postal for information. LINDELL AUTO SALES CO., 3444 Lindell Ave., St. Louis, Mo.

TWO Steptoe 18 in. x 10 ft. engine screw cutting lathes, $100 each; fine for garage repair work. Address, WOODWARD MACHINERY CO., 621 Main St., Cincinnati, Ohio.

FOR SALE—Dealer in new and second-hand automobiles; Ford runabout, 4 cyl., 26 H. P., top, windshield, rumble seat. Maxwell runabout. Oldsmobile, 4 cyl., top, 5-passenger, and windshield. Rambler, 2 cyl., top, 5-passenger, and delivery body, all in good condition. F. B. ARDRIE, 21 Carnes St., W. Lynn, Mass. P. S.—Wanted—to buy 50 automobiles.

WANTED—5 pass. car, 1911 or 1912 model; will trade 20 acres fruit land, Palm Beach Co., Florida. Address, BEN. H. HARMS, Platteville, Wis.

FOR SALE—One 1912 Pierce-Arrow, 48 H. P., seven passenger, Brewster green, run less than 500 miles. C. E. KEMP, 306 Locust St., Williamsport, Pa.

WANTED — Experienced automobile salesman, who could act as sales manager and handle men for concern having a large number of sub-agents and handling 500 automobiles of standard make. Address, giving past record and salary wanted, BAKER, care Motor World.

ONE new seven-passenger aluminum auto body complete with top; upholstering fine shape, color maroon. KNOWLTON WAREHOUSE CO., 93 Perry St., Buffalo, N. Y.

SITUATION WANTED — Acquainted with all branches of automobile work. Eight years of gilt edge reference as a general practical machinist foreman. HENRY ROOK, 428 Park Pl., Brooklyn, N. Y.

STEAM Vulcanizing Plant, complete, cost $200. Quick sale, $25. 3528 N. 27th St., Omaha, Neb.

FOR SALE OR EXCHANGE, for automobile, not earlier than 1911 model, 40 ft. motorboat, 12 ft. beam, 2½ ft. draught, 6 ft. headroom cabin, sleeps four comfortably; toilet, wash basin, dory, 15 h. p. 2cylinder Mianus motor; thoroughly equipped in every way, with full inventory; in commission; price, $800. Apply to E. SHUTTLEWORTH, 815 Vernon Ave., Long Island City, N. Y.

SEVEN passenger car, three months in use, 1911. $2,500. H. CLARK, 292 East 135th St., New York City.

I WILL BUY FOR CASH automobile tires, accessories and supplies in any quantity. E. C. CORNWELL, 369 Normal Ave., Buffalo, N. Y.

AUTOMOBILE Troubles and How to Remedy Them. Cloth $1.00; flexible leather $1.50. Automobile Driving Self Taught. Cloth $1.00; flexible leather $1.50. Guarantee with every book. Send for circular showing other Practical and Mechanical books. AUTO INFORMATION BUREAU, Box 704, North Tonawanda, N. Y.

ONE 1-ton 20 horse and one 2-ton 30 horse new auto trucks at a bargain. CEDAR RAPIDS AUTO WORKS, Cedar Rapids, Ia.

LET us put a good top on your runabout for $14 or touring car for $27; satisfaction guaranteed. BISON TRIMMING CO., Buffalo, N. Y.

AGENTS WANTED — To handle the $1000 G. J. G. "Junior," racy, classy and specially designed chaseabout with 104-inch wheelbase, with a real 26 H. P. motor, Bosch magneto, Dorian remountable rims with 32 x 3½ tires, at a price of $1,000, which is a money-maker for the sales agent. Write for literature and discounts to G. J. G. MOTOR CAR COMPANY, White Plains, N. Y.

BROKEN CRANKSHAFTS, cylinders, crankcases, flywheels, gear teeth, pistons, perfectly welded and machined ready to replace. Guaranteed and references. Machinery up to 5 tons welded. ATLAS WELDING WORKS, 74-76-78 Irving St., Rahway, N. J.

WILL SELL Special Racing Roadster exceptionally cheap. Has Rutenber 30 H. P. motor, unit power plant, with selective 3-speed transmission and Raybestoc multiple disk clutch. Full floating rear axle, 20-gallon gasolene tank at rear, tires in good condition, Bosch dual magneto, and windshield. WESTERN MOTOR CO., Marion, Ind.

SCHACHT RUNABOUT — First-class condition; cheap. DUHLMEIER BROS., Wade and McLean Ave., Cincinnati, Ohio.

Weed Chains

The Great Anti-Skid DEVICE

Nine-tenths of all accidents to automobiles are caused by skidding or slipping.

Either you skid into the "other fellow" or the "other fellow" skids into you.

No matter how careful a driver you may be, you cannot prevent skidding or slipping on wet, muddy snow-covered roads or on icy, slippery greasy pavements unless you equip your car with Weed Chains.

Cannot Injure Tires

Because They Creep

An absolute necessity on both rear wheels and if you want to know what real steering steadiness means put them on the front wheels too.

For your own safety—for the safety of the public, fully equip your car with Weed Chains. Make it your business to get a set today.

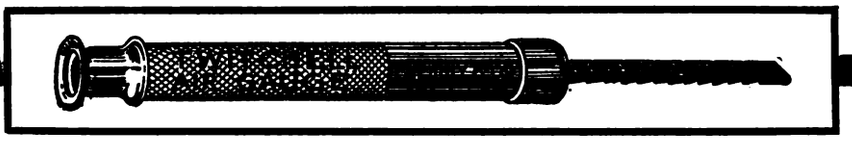
Kelly-Springfield
Automobile Tires



The wear you get out of a tire depends absolutely on the wear the factory puts into it.

The wear the factory puts into a tire depends in turn on the composition of rubber that is used in the making.

The experience of seventeen years of rubber tire manufacture has gone directly into perfecting the rubber composition used in Kelly-Springfield Automobile Tires.

We have reason to believe that there is no way on earth to make a pneumatic tire that will give more mileage and better service under actual road conditions than the Kelly-Springfield.

Kelly-Springfield Tire Company, 20 Vesey Street, New York

The New Twitchell Positive Lock Stop Gauge

There are many types of Gauges on the market, but do you really know of any that are accurate?

We Know Your Answer

Now listen to what we have to say about the NEW TWITCHELL POSITIVE LOCK STOP ACCURATE GAUGE:

1—Correct pressure is insured in all your tires.
2—Its construction is simple.
3—No rubber washers to wear out or deteriorate as in all other Gauges.
4—Absolutely no friction or wear on internal or external parts.
5—In testing this Gauge it passes through four different hands, the last test being inspection.

GET MILEAGE! Correct pressure, and pressure in all your tires are essential to your mileage.

The use of the new Twitchell Air Gauge enables you to attain this. IT IS ACCURATE, SIMPLE AND INSTANTANEOUS, made to carry in the vest pocket and is only 3½ inches long.

No better tire insurance could be produced than a LOCK STOP FEATURE TWITCHELL AIR GAUGE. It can be just as easily read at night as day—the graduated bar remains at the pressure indicated until a slight pressure of the thumb on the extreme end of the ratchet side returns the register to zero.

Correct Pressure for Tires:		
2½"	Tires.....	50 lbs.
3"	Tires.....	60 lbs.
3½"	Tires.....	70 lbs.
4"	Tires.....	80 lbs.
4½"	Tires.....	90 lbs.
5"	Tires.....	90 lbs.

THE TWITCHELL AIR GAUGE IS TIRE INSURANCE FOR ONE DOLLAR.

Can be Obtained from Your Dealer.

FEDDERS

AUTOMOBILE **All Sides Surrounded by Water**

REAL square tube radiators—such as the Fedders—do not clog up and lose their efficiency after a few months of use.

The water channels are both vertical and horizontal. This not only helps to obviate the danger of clogged tubes but insures the maximum cooling surface as well.

Real square tube radiators are easily repaired in the event of an accident whereas most other types call for a return to the factory or an unsatisfactory job. A pair of tinner's irons is all that is needed to repair a square tube radiator.

Every Business Man Is a Prospect for the International Commercial Car

Every man who wants to make quick deliveries, who has to transport tools or material for his work, or who has any kind of light hauling to do, is a prospect for an International Commercial Car.

The selling field of this handy, dependable auto wagon is unlimited because of its general usefulness, and because it gives such universal satisfaction. Wherever a sale is made it helps to close others. The endless chain thus formed makes the selling of this car the best opportunity of the present time for automobile dealers who see the trend of the times toward motor cars as business wagons.

The International Commercial Car has been justly called the car of wide appeal. Grocers, bakers, laundrymen, florists, painters, decorators, carpenters, contractors, plumbers, and men in a hundred other lines of business buy this car because of its fair price, low upkeep cost, efficiency and economy.

Any dealer who will distribute our selling literature among the business men of his town, or the farmers of his neighborhood, and will follow up that literature with practical demonstrations of what an International Commercial Car will do, can make a gratifying success of an agency for this car.

We invite correspondence from live dealers who want to be shown. Address a post card to

INTERNATIONAL HARVESTER COMPANY OF AMERICA, Inc., 155 Harvester Bldg., Chicago, U. S. A.

Self Hanna Starter

Watch the Prices Drop!

Just as the Hanna self starter—the only 100% efficient **self** starter that does not foul or soot your plugs—**was imitated** by those who followed our lead so now is **the price** of the Valentine manifold starter being met.

Remember We Were the Originators

Not only were we the first to produce an acetylene **self starter but** we were first to introduce a manifold **self starter at** the right price, $10.

Our Price Does Not Cut the Dealer's Profit

Still some fine territory open. The profit is big. Our **goods are** right and fully guaranteed. Write today.

Mr. Automobilist:

Your tire maker is very anxious to impress upon you the importance of

Tires Inflated to the Right Pressure

He insists that this is tire economy and

Saves You Money

How do you know what pressure you have in your tires? A

SCHRADER
UNIVERSAL
Tire Pressure Gauge

(Trade Mark Registered in U. S. Patent Office)

(Patented March, 1898—Other Patents Pending)

will tell the exact pressure in your tires at any time, day or night, by simply holding this Gauge to your Valve for a second. Its recording sleeve remains in place, showing the exact pressure in the tire so that the Gauge can be taken anywhere and read, at night to the front of the car into the light of the lamps. After the pressure has been ascertained the Indicating Sleeve can be pushed back into the Gauge with your finger. No catches or snaps to operate or get out of order. This Gauge is 2½ inches long over all, short enough to apply easily to the smallest diameter of wheel and can easily be carried in the vest pocket or the change pocket of your trousers.

Price $1.00 Each

"Look at the rear springs"

if you want to know why some cars ride so comfortably — why comfort is possible when only one or two persons ride in a 7-passenger car.

It's because they are equipped with

"J. M." SHOCK ABSORBERS

which not only *absorb* all jolts and jars, but *actually prevent* them.

By keeping the rear wheels on the ground, the "J. M." secures continuous traction, and eliminates:

First—Racing of the engine when the car jumps the ground.

Second—Grinding of the tires when they hit on the rebound.

This means maximum comfort, increased engine efficiency and decreased tire expense.

Made in three models—attachable in an hour, detachable in fifteen minutes.

Prices, $35 to $50 per set. Write for booklet W, with full information.

The Niagara Self Starter

The Niagara Self Starter does not soot or foul your spark plugs, because it mixes the acetylene gas with pure air and forces this mixture into the cylinders of the engine.

Acetylene gas alone deposits soot thickly in your cylinders and upon your spark plugs. Avoid using starters which depend upon pure acetylene gas. Use only the Niagara Self Starter which mixes this gas with the proper proportion of PURE AIR.

The compressor of the Niagara Starter is made of seamless drawn steel tubing with a cast iron piston and two cast iron piston rings.

Factories and agents should write us for our proposition.

THE NIAGARA SALES CO., Buffalo, N. Y.

Schafer Ball Bearings

are built to withstand the most extreme strains and stresses of hardest service.. The durable, wear-resisting chrome steel used in their construction is of exclusive analysis, free from blisters, air bubbles and every intrinsic weakness that might cause the balls to vary in weight, size or structural strength. The balls are uniform to within .0001 part of an inch and remain so over long terms of hard service. Recognized by engineers as the highest grade and finest quality of anti-friction bearings made today. When you equip with Schafer you insure your car against frictional deterioration.

K·D
The Motor With the Sliding Crescent Valve
KNIGHT-DAVIDSON
1896 — 1912

The CRESCENT valve of the K-D Motor, fitting around the stationary piston wall affords a larger port area than any other poppet or slide valve on the market. It is simpler and, consequently, better than any other valve construction known and is here offered to discriminating manufacturers, not as an experiment, but as a tried, tested and proved mechanical advance. The K-D motor is simple, silent, cools rapidly, has the simplest oiling system known, will not carbonize. Last and most important, will give on a given quantity of fuel more power, speed and endurance, unit for unit, than any other engine on any type of an automobile. We want to present some facts to interested manufacturers.

If You Need Motor Lamps

You Need This Catalog

We want you to write for the Solar Catalog before you decide on your motor lamps, for this is the most complete line of lamps on the market. Solar Lamps have been preferred by most motorists for the past fourteen years because of their brilliancy, their style, their strength and their several exclusive advantages—their special short focus lead glass lens mirror reflectors—the patented double ray light projection (in the Solarclipse), giving two distinct fields of light, for city and country use—the new black finish, the only such finish that's proof against heat and moisture—and other features that other lamps lack.

To fail to see Solars before you buy is to fail to include in your consideration the very finest lamps in existence. Solars are made for oil, electricity, gas and in combination, for pleasure cars, motor trucks, carriages, motor boats and airships. Write for catalog now—while you think of it. (136)

How Much Longer

The Car Agent asks the Manufacturer

Car Agent: When are you people going to give us some kind of a real signal in place of that out-of-date bulb-horn?

Manufacturer: That's hard to say. As soon as the prices come down within reach. Or the pressure from buyers becomes so strong that we have to.

Car Agent: The pressure is pretty strong—*right now*. And as far as prices are concerned what good is our claim that no expense has been spared to provide the *best*—of *everything*—if this affects the adoption of an efficient signal? Should not '*best*' apply to equipment as well as to construction?

Manufacturer: Well, you know there's a mighty big difference between the cost of a bulb-horn and a signal like, for instance, the Klaxon—and this is what you say most buyers insist upon. The bulb-horn we put on now costs us about an eighth of what the Klaxon would cost.

Car Agent: That's all right—as long as you can get away with it. But you can't do it much longer—motorists are getting too wise—they know too well what a farce the bulb-horn is. The brunt of the deal falls on us. Other makers supply the Klaxon. Customers know it. Right along, to make a sale we have to give them one, and take its cost out of our commission.

Manufacturer: Don't do it. Make them buy the Klaxon *themselves*. Tell them it's a *luxury*.

Car Agent: They know better. That's what we've been telling them for a couple of years. You can't argue with them any longer on that score. They know—as well as we do—that it's a *necessity*. Why as far as that is concerned—we have one on our demonstrating car. Have to. Simply cannot do without it. You can't make a good demonstration—you can't drive a car—and drive it *right*, unless you *do* have. Buyers know this. They see the Klaxon there—ask if it's regular equipment—and, well, it's mighty hard to explain to them why it isn't.

Manufacturer: Sell them the *car* then—on its merits. Make them *forget* the equipment.

Car Agent: That's all right to say—but nowadays it doesn't work. There are too many good cars whose agents *do* talk equipment—who *give* them the things we *charge* them for.

Manufacturer: Well, it probably won't be for long. Sooner or later we will come to it. We have been staving it off. But I guess we can't do it much longer. We will try it another year and see what happens. Then maybe we will put on a "buzzer" or something—to satisfy their protest against the bulb-horn.

Car Agent: If you think you can satisfy the average car buyer with anything less than the Klaxon, I believe you are mistaken. They know it too well. They know it's the only signal—and to try to hand them anything else would make it harder even than at present. Besides, it's a confession of cheapness which reflects on the car. We must give them the *best* or nothing at all.

26 *different makes of motor cars now carry the Klaxon in their regular equipment. The agents of many of the others supply it without charge to customers that emphatically insist.*

Studebaker

Flanders "20"

Suppose we deliver a "20" at your door tomorrow—

Touring time is here; and you feel the urge of it.

Telephone the Studebaker dealer and have a "20" sent out tomorrow.

It will cost you $800—or $885, if it's fully equipped.

And what will you get—will you get $800 worth?

Well, we don't know of a better $800 worth in the world.

We'd say that, even if you judged it only from the standpoint of size; and good looks; and workmanship; and material; and generous specifications.

But that isn't the main point.

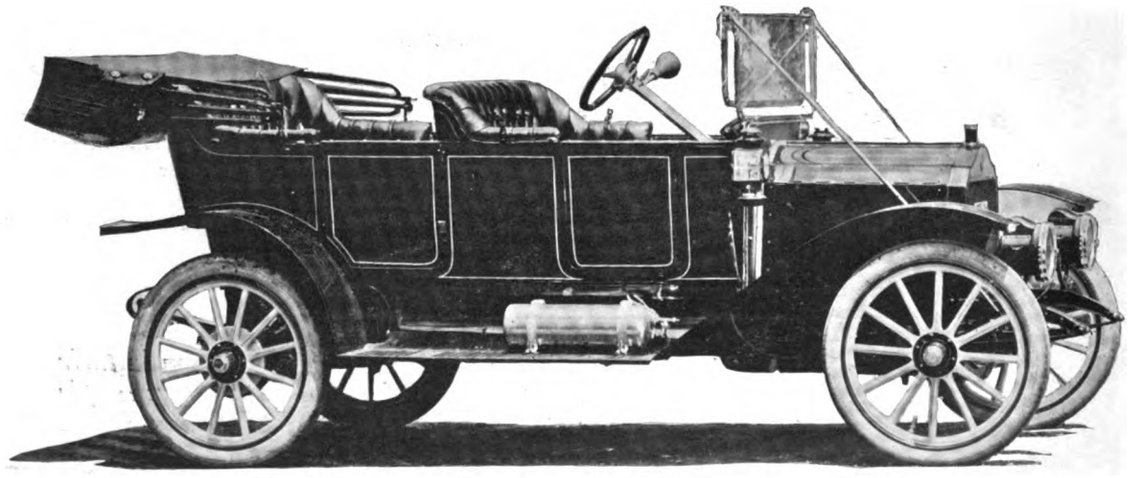
The thing that ought to bring you to a decision to send for the "20" tomorrow is the certainty that you're not taking a chance.

It might be wise to take more time if the "20" were just a motor car.

But it's infinitely more than that — it's a Studebaker motor car.

Seventy-five thousand other owners have preceded you in the Studebaker 'testing out' process.

Sixty years of faithful performance have made the Studebaker word as good as gold.



Enormous productive capacity and world-wide distribution make the price right.

Yield to that impulse to get a car at once.

You're made absolutely safe by that name Studebaker.

Telephone the Studebaker dealer.

Take the children with you when you get the first demonstration tomorrow.

Studebaker Flanders "20" Touring Car

$800 F. O. B. Detroit, standard Equipped.

THE MOTOR WORLD

A Trade Paper Giving the World's Motor News

Vol. XXXII
No. 5

New York, July 25, 1912

Ten cents a copy
Two dollars a year

Stoddard-Dayton "48"

Stoddard-Dayton Automobiles
1913 Announcement

STODDARD-DAYTON AUTOMOBILES for 1913 will be known chiefly for their luxury, beauty and comfort. Four models, embodying refinements developed through nine years of successful production, are presented. They follow in general design, beauty of finish, completeness and excellence, those features which have always guaranteed to Stoddard-Dayton owners cars as durable, capable and satisfying as can be built. The Stoddard-Dayton "Knight," the only six-cylinder car built in America with the Silent Knight motor, the Stoddard-Dayton "48," "38," and "30" give a range in size, power and price which accommodates all desires.

We know that the 1913 Stoddard-Daytons offer extraordinary values in strictly quality cars, and that the distinct pride of ownership enjoyed by those who have driven Stoddard-Dayton cars will continue with increased measure.

1913 Specifications

Stoddard-Dayton "Knight"—$5000

The highest achievement of the science of automobile engineering. Seven passenger touring car; six cylinders, 70 hp; left-hand drive, center control; wheelbase 133 inches; tires 36x5; Q. D. demountable rims; selective transmission; electric lights and horn; Hartford shock absorbers; mohair top and boot, storm curtains; rain-vision windshield; speedometer; seat covers; tools, jack, trunk rack; tire holders; color and upholstery choices. Knight Compartment Roadster, $4900; Limousine $6250.

Stoddard-Dayton "38"—$1850

A large, powerful, quiet car, of a renowned family, at a moderate price. Five passenger touring car; four cylinder, long stroke motor, cast en bloc, 38 hp; wheelbase 114 inches; tires 36x4; Q. D. demountable rims, selective transmission; gas head lamps and tank, oil side and rear lamps; mohair top and boot, storm curtains; windshield; jack, tools; color choices. Compartment Roadster $1750; Coupé, inside drive, $2350; Limousine or Landaulet $2750.

Stoddard-Dayton "48"—$2800

The car with the famous valve-in-head flexible and quiet motor. Seven passenger touring car; four cylinders, 48 hp; wheelbase 123 inches; tires 36x4½; Q. D. demountable rims; selective transmission; gas head lamps and tank; combination oil and electric side and rear lamps; Hartford shock absorbers; mohair top and boot, storm curtains; rain vision windshield; jack, tools; color choices. Compartment Roadster $2700; Limousine $3900.

Stoddard-Dayton "30"—$1450

A "smaller" Stoddard-Dayton with the lines, appearance and careful finish of the larger cars. Five passenger touring car, four cylinder, long stroke motor, cast en bloc, 30 hp; wheelbase 112 inches; tires 34x4; Q. D. rims; selective transmission; gas head lamps and tank, oil side and rear lamps; all metal trimmings nickel plated; mohair top and boot, storm curtains; jack, tools, color choices. Compartment Roadster $1350.

DELIVERIES NOW *Dealers everywhere are prepared to make deliveries of the touring car and roadster models at once. We will be glad to send you the Advance Catalog for 1913. Write for it.*

F-400 Slip Hubs (30% Carbon Steel)

Another group showing part of an order from one of the best known car concerns in the country—all now assembled and delivered as per time clause, as usual.

Nowhere, in the field in which we operate, is there a maker of universal joints and cone clutches, that can "promise and perform" along lines upon which we operate.

Here we follow your specifications, beginning with material of your selection—heat treatment according to your formula, design as per your laid down lines, forging, machining and finishing subject to your smallest requirement. And then F. O. B. Hartford on date demanded. Not sometimes, but always.

In fact, our shops are part o your plant for the time being, and from them come your products, flawless, and correct in every detail.

Scores of pleasure car and truck builders—all representative in the field—will attest to the correctness of this statement.

We stand ready to become a temporary part of your organization—from our engineering department on down to the raw material department.

EXPERIENCE - SHELDON - RIGHT DESIGN
FACILITIES — AXLES — RIGHT STEEL

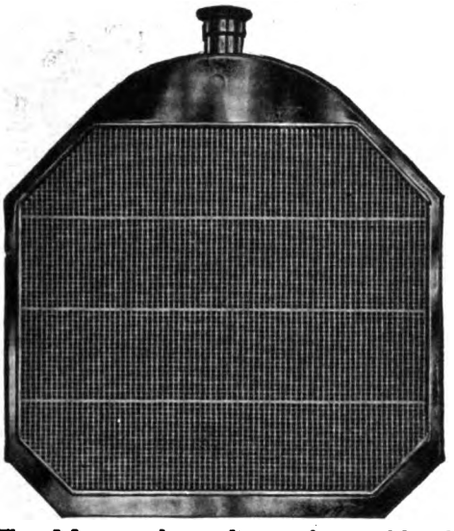
"Made in the Largest Axle Factory in the World"

Axle Talk—No. XII

Our plant turns out seventy-five per cent of the axles used on commercial cars, and this fact alone presupposes quality production beginning with design and material and ending with service.

The truck axle has a pretty hard time of it. It's relative work as compared with a pleasure car axle, being in the same ratio as that of a heavy dray horse as compared with the pacer in a light rig.

Load on a truck means more direct stress, corresponding road shock and violent side thrust, while solid tires still further add to the trials of the commercial axle.



Pound for pound the truck axle ought to be better built and stronger than pleasure car design—it remains that some of them don't measure up to this standard.

There is a certain well defined reason for SHELDON supremacy in the commercial car field—also a reason accounting for the fact that pound for pound SHELDON pleasure car axles are in the same class with their big brothers. Quality is that reason.

McCue Wire Wheels and McCue Axles

This combination means the most advanced motor car design and construction that progressive manufacturers can select.

The superior of McCue axles does not exist.

McCue axles are designed especially for cars requiring rigid yet light construction. The overload allowance is extremely liberal and the additional factor of safety is extremely high. The driving shafts are so designed as to divide the carrying and slewing load with the center bearing. All bearings are extremely large and of the highest grade possible to obtain. Special attention is given to the mounting of these bearings and in the calculation of the bearing size in relation to weight, the question of the shaft diameters is carefully considered. As a result, we have never had a broken differential housing or axle tube, even though many of our axles have been used on cars weighing 50 per cent more than the capacity for which the axles were designed.

Wire wheels, of course, are certain to be standard equipment on many American cars within a very short time. They have come into their own abroad and are fast being taken up by the progressive American manufacturers.

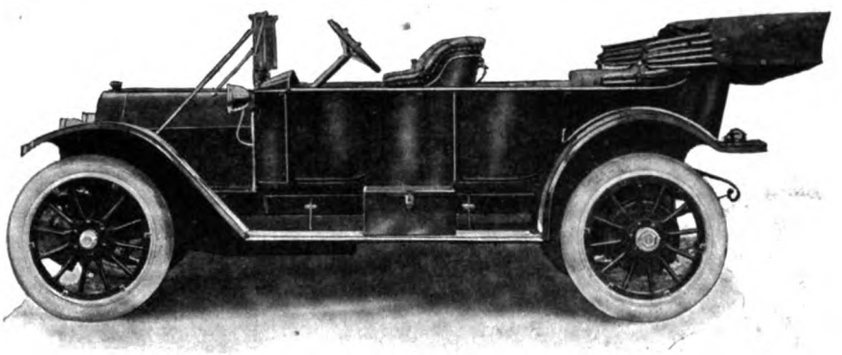
Wire wheels are acquiring their prestige solely from intrinsic merit, for any one improvement which will enable car owners to realize practically *70 per cent more tire wear than without the improvement is bound to become standard.

This is what wire wheels do.

They are the greatest conserver of tires brought out since the beginning of motor cars.

Not only do wire wheels mean economy to car owners but they mean more car owners and more car sales for dealers and manufacturers.

The McCue Company is a pioneer in wire wheel construction in this country.



McCue axles will admit of the use of either wire or wooden wheels on the same spindle.

* In a SIX MONTHS TEST conducted by the ENGLISH DAIMLER Company, wire wheels showed an ACTUAL tire SAVING of 68.75 PER CENT.

THE McCUE COMPANY, Buffalo, New York

Pullman

BACK of every Pullman car and working hand in glove with Pullman agents is the most perfected sales making organization in the industry.

Long ago the Pullman Company realized that the average Dealer doing business on the usual discount was at a disadvantage. His net earning on each car was none too large and each year the buying public demand more and more for their money.

The Pullman Company proceeded to apply the remedy, there was but one answer.

Reduce the Agent's Overhead Selling Expense

The present honestly built automobile cannot be overpriced—competition will not allow it—likewise the manufacturer who has already "gone the limit" cannot allow the Dealer a larger discount.

We anticipated this condition with the result that Pullman agents always have a tremendous advantage over competition.

Send for "Blue Print" of our "Sales Making Machinery"—learn more about our modernized sales methods. We spend thousands of dollars in locating your prospective purchaser in advance—we get you in touch—our selling plan is unique and will be mailed on request.

Every Pullman a Real Leader for 1913. All Fully Equipped

SPLITTING Hairs at the Timken Plant

It is literally necessary to split hairs to illustrate the extreme accuracy of the manufacture of Timken Roller Bearings.

An accuracy and care that came after Timken Bearings had won their way on the sheer merits of their unique principles of design alone.

TIMKEN
TAPERED ROLLER BEARINGS
are made with as much care as a watch

Take the gauging of the rollers for instance. Every roller in a Timken Bearing must be just the size of every other roller.

It would never do to trust the gauging of the rollers to human hands. Human liability to err is too great. The mechanical perfection of Timken Bearings is a matter of too much pride with us.

So we designed and built machines that take the rollers after they have been hardened and ground to the limit of human accuracy and sort them into lots in which every roller is the exact size of every other roller.

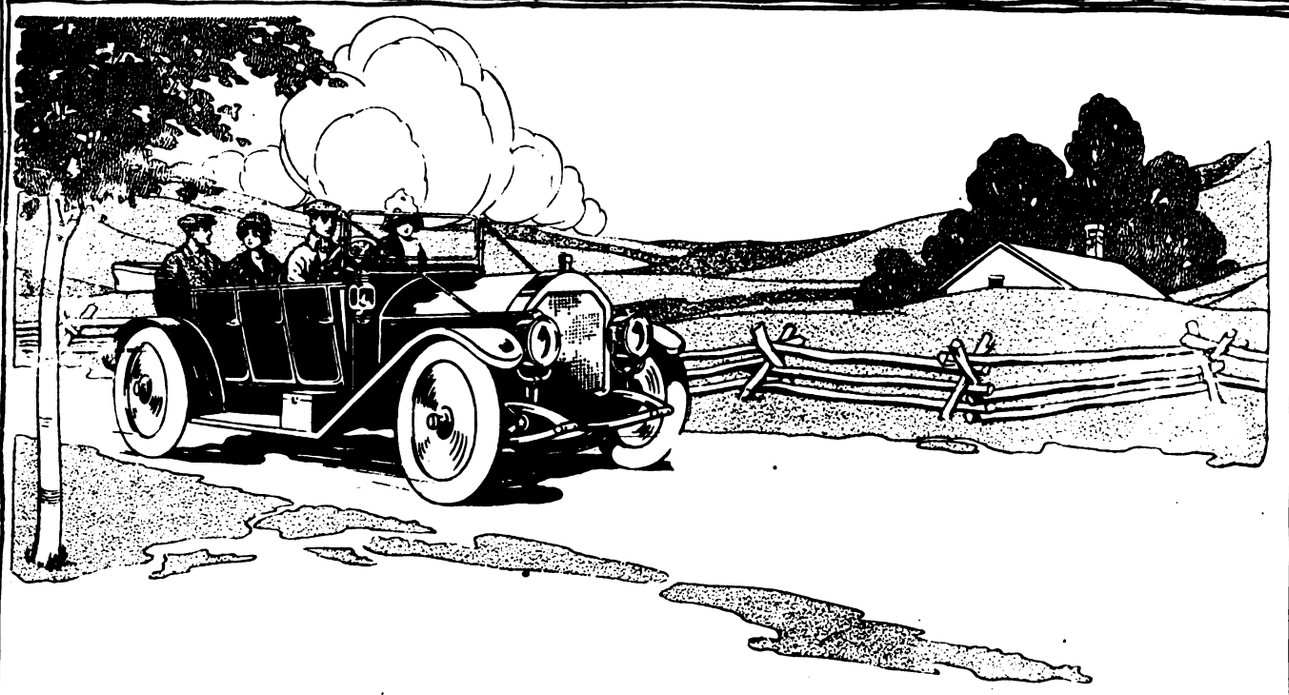
The machines do not err—they do not depend on human eyesight or judgment.

They distribute the rollers with unerring accuracy to different containers. The separation of the sizes is purely mechanical, and electrical. Electric contact decides which container each roller shall enter.

When the gauging is finished each container holds rollers of the same identical size. The containers are sealed till the workman assembles his bearings. Then he knows positively that every roller is right.

This is just one example of the care in making that assures you not only the bearing with all the correct principles of design, but the bearing that is built with the utmost accuracy.

This is one of the reasons why Timken Roller Bearings are giving such satisfactory service in the cars of the great majority of American pleasure and commercial car builders.



The list of Timken Users names nearly every good car that you know. Printed in a booklet called "The Companies Timken Keeps." Send for a copy today.

The Timken Roller Bearing Company
Canton, Ohio, U. S. A.

The only axle manufacturer licensed to make automobile axles equipped with Timken Roller Bearings is the Timken-Detroit Axle Company

R-C-H "Twenty-Five"

$900
f. o. b. Detroit

The Car

WHEELBASE—110 inches.

MOTOR—Long-stroke; 4 cylinders cast en bloc; 3¼ inch bore, 5-inch stroke. Two-bearing crank shaft. Timing gears and valves enclosed. Three-point suspension.

STEERING—Left Side. Irreversible worm gear, 16-inch steering wheel. Throttle control on steering column.

CONTROL—Center Lever operated through H-plate integral with universal joint housing just below. Hand-lever emergency brake at driver's right. Foot accelerator in connection with hand throttle.

SPRINGS—Front, semi-elliptic; rear, full elliptic and mounted on swivel seats.

FRAME—Pressed steel channel.

AXLES—Front, I-beam, drop-forged; rear, semi-floating type.

TRANSMISSION—3 speeds forward and reverse; sliding gear, selective type.

CONSTRUCTION—Drop-forgings wherever practicable; chrome nickel steel used throughout all shafts and gears in the transmission and rear axle; high carbon manganese steel in all parts requiring special stiffness.

BODY—Full 5-passenger English type; extra wide seats.

The Equipment

Non-skid tires, 32x3½.
12-inch Hall Bullet electric head lights with double parabolic lens.
6-inch Hall Bullet electric side lights with parabolic lens.
Exide 100 Ampere Hour Battery.
Bosch Magneto.
Warner Auto-Meter.
Demountable rims.
Extra rim and holders.
Tally-ho horn.
Jiffy curtains—up or down instantaneously.
Top and Top cover.
Windshield.
Rear view mirror.
Tool-kit, Jack, Tire Repair Kit, Pump.
Robe Rail.

THE car you handle is either an asset or a liability in your business.

On every automobile row this condition is vividly illustrated. You'll hear: "Brown is handling the ——— car and making a lot of money." And a little further on: "Smith represents the ———, but he isn't doing much."

The one dealer is prosperous; the other, on the ragged edge of failure. One is handling a car that appeals to the public; the other, a car that will not stand the acid test of public criticism.

The R-C-H appeals to a wider range of buyers than any other car on the market today.

The man who would ordinarily buy the lowest priced car he could find is so attracted by the wonderful value in the R-C-H that he is easily induced to spend a little more for a great deal better car. And the man who would ordinarily pay six or eight hundred dollars more, finds in the R-C-H everything essential to his motoring enjoyment and satisfaction. So he keeps the difference in his own pocket.

Any dealer who reads the specifications and equipment of the R-C-H, and considers the demands of his own clientele, knows these facts to be true.

From such dealers we invite prompt correspondence regarding open territory.

One Look Tells Everything

The JEFFERY-DEWITT CO. DETROIT, MICH. Visible Spark Plug lays bare all ignition troubles

The "visible gap" is an open "window" giving you a full view of the internal workings of your spark plug.

If the spark is seen jumping the gap, look for your trouble between the gap and sparking point.

If there is no spark in the gap, your trouble is behind the plug—in Magneto, or batteries, or coil, or wiring.

But for the "visible gap" it would take you many precious minutes —often hours—to locate the seat of trouble.

$1.00 Buys this great new Spark Plug

Indicates in which direction trouble lies.
Facilitates timing of engine.
Intensifies spark in cylinders.
Consumes only minimum current.
Gap adjustable—can be closed entirely.
By widening gap plug cleans itself.
Permits regulating spark for any cylinder.
Costs same as any good plug—$1.00.

Dealers will find J. D. Visible in greatest demand

Visible Idea Worked Out Perfectly for the First Time

The "visible gap" feature, so far as being incorporated in a plug, has always seemed as far away as perpetual motion. The visible feature has been marketed in a separate device for years, but this is the only plug in which this important visible feature is actually embodied.

It is simple. Merely a hole in the porcelain and a spiral action to regulate width of the gap in the central electrode which carries the current.

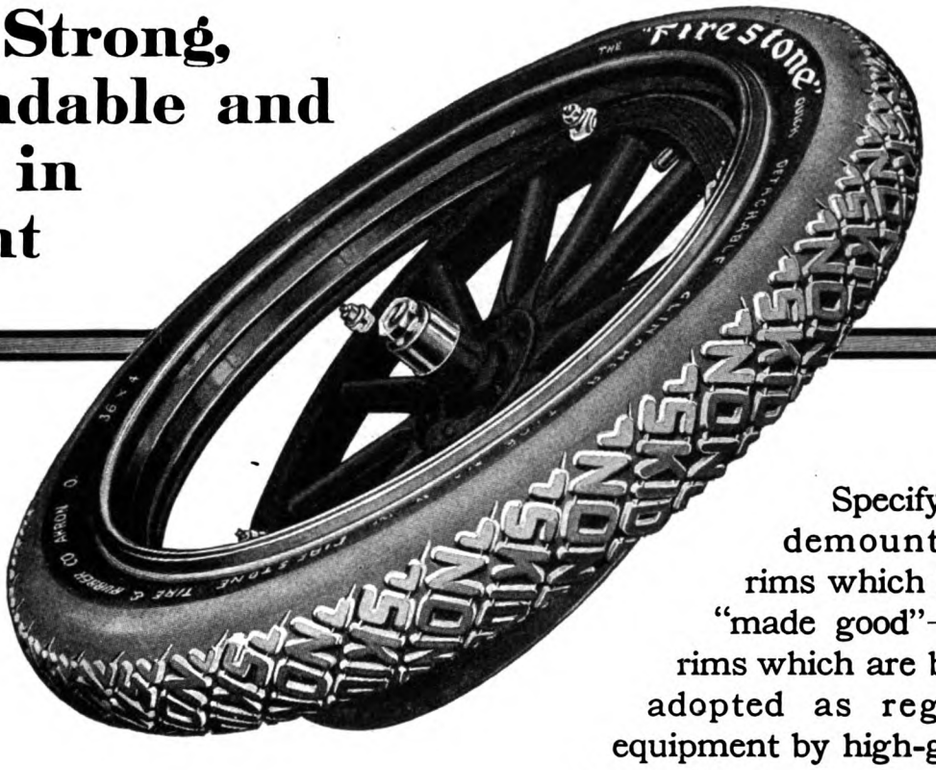
The hole in no way lessens the strength of the plug, and the current in jumping the "visible gap" loses none of its efficiency. On the other hand it intensifies the spark at the gap in the cylinder.

Additional prestige is lent the J. D. Visible Spark Plug by the fact that it is being introduced by the largest manufacturers of spark plugs in the world. We are exclusively manufacturers of spark plugs; we make millions of them each year.

The J. D. Spark Plug was a famous plug before it was improved by the visible feature. It combines finest workmanship, best materials and simplest designs.

Every part of this plug is made in our factory—even the porcelain being produced in our own potteries from clays and other ingredients imported from Europe.

This unequivocal guarantee goes with all our spark plugs:



"Your money back or a new plug if you are not satisfied."

If your dealer hasn't the J. D. Visible yet, send your money direct to us for a set, specifying size wanted and make of car, and we will ship them postpaid. Remember, the J. D. Visible Plug is $1.00. Our literature on ignition free for the asking.

JEFFERY-DEWITT COMPANY, 565 Butler Ave., Detroit, Mich.

K-R-I-T

Model "K" Touring Car, Fully Equipped—$900

Equipment includes three oil lamps, two gas lamps, generator, top with side curtains and top cover, windshield, horn, demountable rims with spare rim, tool kit with jack and tire repair outfit with pump.

The K-R-I-T is always a new car

One of the main elements of the extraordinary K-r-i-t value is the fact that the K-r-i-t is always a new car.

We employ an efficient corps of engineers and designers to devise improvements and refinements.

We install these improvements and refinements as rapidly as our engineers develop them, instead of holding them back for introduction on the next year's model.

So the K-r-i-t owner, at the beginning of a so-called "new season," as at all other times, finds himself with a car in which the latest practical ideas have already been incorporated.

The K-r-i-t car—every K-r-i-t car—has been brought up to the current moment in the motor car industry. We announce no sensational new model because every K-r-i-t car is new.

This policy is as old as the Krit Company.

We adopted it at the outset because we believe the buyer is entitled to the most modern in design, construction, or progress—no matter when he purchases his car.

Because of this policy, we make no "new season" announcements; and will make none this year.

And because of this policy, the purchaser of any K-r-i-t, at any time, is assured of getting a car that embodies the latest and best in engineering practice and in design.

Where the K-r-i-t gets its extraordinary power, extreme durability and long life

The K-r-i-t's reputation for staunchness and extreme durability is not confined to a few isolated communities, as you probably have learned.

It is as wide as the nation; and the rougher the country, the more difficult the roads—the more firmly the K-r-i-t is established as the medium-priced car that has made good.

The chief of the reasons for this is, of course, the structural quality of the car.

But back of this, and overshadowing in importance every other consideration, lies the fact that every part essential to smooth running, long life, economy and comfort, is produced by and within the K-r-i-t organization.

In other words, the K-r-i-t at $900 is a manufactured car in a sense as binding and literal as the term implies when applied to the $4000 or $5000 car.

You see how this process of manufacturing, instead of buying parts ready-made and assembling them, saves money for the manufacturer.

And the saving, in this instance—in the shape of better materials, more careful workmanship, better operative qualities—goes into the K-r-i-t and makes it a vastly better value than the average $900 car.

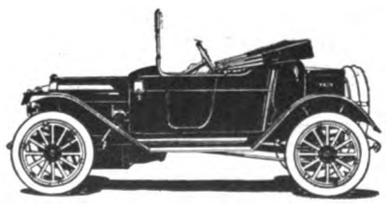
We not only design the motor—we make it; cast the cylinders in one piece to give rigidity and preserve alignment; equip it will ball bearings and with connecting rod bearings 50 per cent larger than usual, to promote smooth running, silence and the greater development of power.

We make the clutch of multiple discs—a clutch that holds, and holds, and holds in sand and mud and on the hills; and yet starts the car as smoothly and easily as an electric glides away.

We make the transmission and rear axle, cut the gears from chrome nickel steel—the hardest and costliest metal known—and mount them on ball bearings.

We drop forge the front axle, thus assuring strength and stability in a most important member.

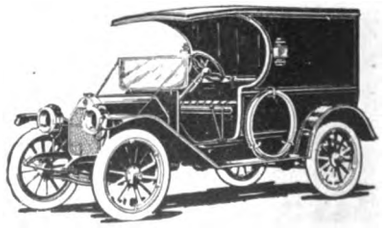
We make the transmission drive shaft of chrome vanadium steel, and specially heat-treat it for toughness and strength.



Turning to the factor of comfort, you find the touring car amply roomy for five grown persons—and equipped with full elliptic rear springs, another unusual feature for $900 to $1000 cars.

At almost every point throughout the K-r-i-t you encounter a value fact that you have not found in other cars of the K-r-i-t price.

To be sure, you may succeed in getting one, or even several, of the K-r-i-t features in some other car of equal price.



But you can't get them all in any car save the K-r-i-t.

Confirm this by a visit to the nearest K-r-i-t dealer; or write for the catalog.

"The Horn that's Made for the Discriminating"

TUTO HORN

THE TWO TONE HORN

Not Paralyzing to Car Occupants.

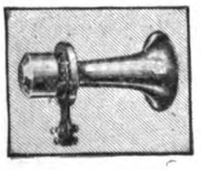
THE loud abrupt warning signal is necessary on the motor car for limited use, such as emergencies.

¶ To forestall these emergencies, a low abrupt signal also is necessary.

¶ Ordinarily this means the retention of the inadequate bulb horn for regular service and the supplementing of it with a second device for producing the loud note.

¶ If the loud note only is employed for all of the signalling of the car, it is extremely objectionable, both to the car occupants and to those outside.

¶ Modern adverse legislation is ample proof that the indiscriminate use of this loud warning note is objectionable to the majority of the people.

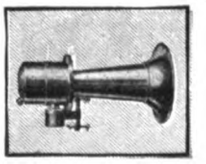


¶ Car occupants, especially women, will not put up with the unnerving, paralyzing note of the inflexible loud warning signal.

¶ The demand is for a low note in addition to the loud note, and before the advent of the TUTO Horn it was necessary to retain the inefficient bulb horn for this milder signal, requiring the confusion and rapid action of going from a bulb to a button when an emergency arises.

¶ The TUTO Horn does all of the signalling of the car by having a low abrupt note which is found to be effective fully 90% of the time, also a loud emergency note which can be produced instantly by a mere increase of the pressure on the same button that is used for the milder signal.

¶ There is no duplicate of accessories and the TUTO is so designed that it can be mounted permanently so as to operate without interruption or attention, as long as the rest of the car.



¶ The TUTO Horn is best for standard equipment as it is the only device which does all of the signalling and in a simple and safe manner.

A Perfect Starter At Last!

Energetic Dealers Wanted

A rare business opportunity. Live dealers throughout the entire world wanted to represent us and to install the National Starter

The First Perfect Mechanical Starter

It has always been said that if a *perfect* starter could be built—a *dependable* starter—one that would start the engine from the seat and forever do away with dangerous cranking—that such a starter would revolutionize motoring—that it would add the final touch of perfection to the automobile.

—and now, after years of experimenting, comes the first *perfect* mechanical engine starter—the NATIONAL STARTER—the *only* starter that is actually 100% efficient.

Works *every* time.

No batteries—no tanks—no wiring—no piping—no springs. Nothing but simple ball-bearing gearing.

Dealers in automobiles and accessories, and garage owners will instantly recognize the tremendous business possibilities of this new starter.

The Principle of the National

The National is built on a patented principle.

It is purely mechanical.

A simple pressure of the foot and the engine turns over—just like cranking.

The powerful leverage which is obtained through gear reduction turns the engine over easily—*so easily that you can start on the magneto just as readily as on the batteries.*

The National works equally well in hot or cold weather. It is *not* dependent upon acetylene gas, compressed air, gasoline, electricity or springs. It develops its entire energy through the slight pressure of your foot on the dash pedal—like a clutch. In case of back-fire the National automatically disengages.

We have subjected the National to the severest tests. We have tried it out in all sorts of weather and on all sorts of cars. We made it *prove* its merits.

And now we back every National with an ironclad guarantee for one year.

Easy to Install—Easy to Operate

The National can be installed on any car in about two hours' time. It is fastened to the front of the car in place of the crank. Total weight is about 15 pounds.

THE NATIONAL GAS ENGINE STARTER COMPANY
Dept. 551B, 30-32 N. Dearborn St., CHICAGO, U. S. A.

Car Owners: *Write us for literature and name of nearest "National" dealer.*

Manufacturers: *Write us for literature and our offer to install the National as standard equipment.*

A ten year old child can operate the National easily. One pressure of the foot—the crank shaft turns—the engine starts. Just a simple mechanical operation.

A Big Business Proposition

The tremendous demand for a *perfect* starter makes the selling end of the National only a matter of proving its merits. *Thousands and Thousands* of car owners will install the National as soon as they see it.

They'll want the advantages of the National for themselves as well as to enable the women-folks to drive.

You see the field is practically boundless.

Big business men consider this a big enough proposition to *open up special demonstrating salesrooms for the exclusive sale of the National.*

They realize the wonderful possibilities of the National.

The retail price of the National is $50.00 *completely installed.* Figure out approximately the number of cars in your territory and you will have an idea as to how broad a proposition this is.

Applications for Agencies Now Being Received

Already we have received thousands of applications for National agencies. We are literally *swamped* with requests. South America, England, Germany, France—energetic dealers in all these countries have applied for National agencies as well as thousands of American business men. But we are prepared to meet the tremendous demand.

THE NATIONAL STARTER
TRADE MARK

We have practically unlimited manufacturing and financial resources.

Agencies for the National Starter are now being allotted. Applications will be handled in the order in which they are received.

Wire us, and come to Chicago if you can—let us show you just how the National is built—let us tell you in a personal interview the tremendous business possibilities of this proposition.

If you cannot come, write us. Full information and large descriptive circular can be had by signing and mailing the coupon.

Sound—Noise

THE ORIGIN OF SOUND is in the "vibratory movements of a sonorous body." For example, the "A" string of a violin to give its natural note must have 435 complete vibrations per second, while the lowest note employed in music ("C" of the 16 ft. organ pipe) has 32 vibrations per second.

HIGH NOTES SOUND LOUDEST to the human ear. In other words, our auditory apparatus is more susceptible to sounds caused by rapid vibrations even though their real intensity is the same as other sounds lower in the scale.

HIGH SPEED ENGINES, wheels covering roads none too good at speeds of forty to fifty miles per hour, and gears transmitting power from the engines to the wheels, all combine to produce in the motor car the rapid vibrations that can only result in excessive noise.

ATTENTION HAS BEEN GIVEN to many of the parts which permit of alteration and refinement to assist in quiet operation. Development of the Knight engine alone has been accomplished at a total outlay of something like one million dollars. Other inventors will shortly be heard from.

SOMETHING HAS BEEN WRITTEN concerning the various causes of gear box and axle noise. For even reasonable quietness the transmission case must of course be properly reinforced. All gears must be reasonably accurate as to form and must be properly mounted. Gear grinding is all right theoretically but it has not as yet attained commercial popularity.

LET US SAY RIGHT HERE that proper mounting is the real secret. This does not mean simply the use of even an admittedly good anti-friction bearing. It means a bearing of maximum efficiency but at the same time flexible enough to relieve the parts from the strains and vibrations of sudden shocks and jars.

THE ONLY BEARING with all the essential qualities—flexibility, efficiency and durability—is the Hyatt.

HYATT ROLLER BEARING CO.
DETROIT, MICHIGAN

FRANKLIN "LITTLE SIX"

$2800

A new type of six—a small one.

Some sixes weigh twice as much. No other six weighs so little and no other is so compact.

Motor only thirty-horse-power—good as sixty-horse-power for what a man wants—the car itself is so light.

It is real work to drive a big car. It is real pleasure to drive a Franklin Little Six.

Many cars are going to more weight. This means harder driving, less comfort and more expense. The Franklin Little Six is the other type—a light car.

Weight and bulk are what the man buys who does not know. The man who does know buys lightness and agility.

Eight people out of every ten, would be absolutely satisfied with a Franklin Little Six.

It costs the least to own, runs the sweetest, looks the best and does the most because it is so practical and convenient.

Newtone Superior

Three Years of actual road test has proven that this new product of the oldest warning signal manufacturing concern in the United States, is the KING OF THEM ALL! Six undeniable points of Superiority in the NEWTONE SUPERIOR are:

Durability Loud, Abrupt Warning Note Accessibility
Beauty of Design Popular Price
Least Current Consumption

¶ It is not a *buzzer* or a cheaply made motor driven horn; it is made of the best materials and embodies the best electrical and mechanical construction. A small electric motor, every running part of which is lubricated by a weatherproof oil cup placed on the outside of the casing, operates on a vanadium steel diaphragm, the vibrations of which generate a powerful note of warning. A very ingenious arrangement of the casing permits easy inspection of the commutator and brushes which are made of a material warranted not to cut the commutator or to accumulate moisture.

¶ The price of the NEWTONE SUPERIOR is the result of scientific BUSINESS MANAGEMENT, and of the great manufacturing facilities acquired with eight years experience in the exclusive manufacture of auto signals. It can be had in Brass, Black and Brass, Nickel or Black and Nickel, all at the same price, $10.00. DELIVERIES WILL BEGIN AUGUST 15th, 1912.

CAR MANUFACTURER: You need this signal for your 1913 equipment.

JOBBERS AND DEALERS: This is a signal that the public will buy; it has no come-back, uses only two amperes of current and is sold at the lowest price.

Automobile Supply Manufacturing Co.

220 Taaffe Place, Near DeKalb Ave. (Incorporated 1904) **BROOKLYN, N. Y.**

Digitized by Google

WE are about to make the greatest bid for your contract signature any automobile manufacturer has ever made. Watch for our announcement. It will appear on August 17th.

¶ No more startling selling proposition has ever been offered than the Overland line for 1913. It will create an unprecedented demand. Overland dealers should break all sales records.

¶ Wait—We will startle the trade.

THE MOTOR WORLD

Vol. XXXII New York, U. S. A., Thursday, July 25, 1912. No. 5

KNOT FOR UNIVERSAL TO UNRAVEL

"Angel" of New York Company Disputes Its Transfer to Detroit Corporation—Seeks to Have It Set Aside.

While the Universal Motor Truck Co., of Detroit, is reorganizing itself into a million dollar corporation, a knot in which it is involved has developed in New York, growing out of its absorption, in April last, of the Universal Truck Co., of New York City, which handled Universal trucks in the metropolitan district. The trouble has taken legal form in two actions, instituted last week in the Supreme Court of New York County by George Wheeler, who still insists that he is treasurer of the New York company, the absorption of which he is seeking to have declared illegal.

Rock-bottom facts are difficult to obtain, as the bills of complaint have not yet been filed or served, apparently awaiting the arrival in New York of Fred K. Parke, whom the proof of service describes as vice-president, secretary, treasurer and general manager of the Detroit company. According to the allegations of the various parties to the proceedings, however, it appears that after the Universal Motor Truck Co. was organized the Universal Truck Co., of New York, was formed by Wheeler and Howard M. Walton, among others, its capital stock being $50,000, of which Wheeler claims to have provided between $30,000 and $40,000. Walton was made president, Wheeler treasurer and Albert Engelhart secretary. Apparently all went well until April 27th last, when at a meeting of the New York company Wheeler was deposed as treasurer and Samuel Mann, one of the company's salesmen, was chosen to fill the vacancy, Engelhart retiring and Wheeler being given the office of secretary. Following this meeting, which Wheeler declares was illegal, the Detroit company absorbed the New York concern, which now exists only as a branch, thus leaving Wheeler in a position not easily definable. Wheeler's side of the case, as nearly as can be learned, is that he provided nearly 80 per cent. of the capital of the New York company—in other words, was its "angel"; that the meeting of April 27th was illegal, and that the taking over of the New York company by the Universal Motor Truck Co., of Detroit, also was contrary to law.

It seems, according to information obtained from several sources, that when the New York company began to deal in Universal trucks, it gave the Detroit company a note for $2,000, putting up its entire capital stock as security. Whether the note was paid is not made clear, but at any rate the Detroit company still holds the stock.

Of Wheeler's two actions, one is directed against the Universal Truck Co., of New York, the Universal Motor Truck Co., of Detroit, Howard W. Walton, Fred K. Parke and Samuel Mann. It seeks to require them to make an accounting. The second action is leveled at the Universal Motor Truck Co. and Parke and demands the return of the New York company's stock.

Bowen Becomes President of Rutenber.

George W. Bowen, president of the Bowen Mfg. Co., of Auburn, N. Y., who recently acquired a large interest in the Western Motor Co., of Marion, Ind., which manufactures Rutenber motors, and who formed the Rutenber Motor Co. to take over the business, has been elected president of the new corporation, which is incorporated under Delaware laws with capital stock of $1,350,000. It is stated that the transaction ultimately will lead to the consolidation of the Bowen Mfg. Co. with the new Rutenber corporation.

Grossman-Vanguard Agreement Ended.

On August 1st next, when the selling arrangement with the Vanguard Mfg. Co., of Joliet, Ill., expires, the Emil Grossman Co., of New York, will discontinue the sale of Vanguard windshields. Thereafter the Grossman company will devote its energies to the production of Redhead spark plugs and its other specialties.

TWO DECREES FOR DYER PATENTS

After Several Delays, Court Orders Judgment by Default Against Palmer & Singer—Liveryman also Beaten.

After several postponements and more than a year of legal quibbling, one of the four original suits instituted by Leonard H. Dyer, who practically constitutes the Enterprize Automobile Co., against as many prominent automobile manufacturers to enforce the now famous Dyer transmission patents, Nos. 885,986 and 921,963, came to a head late last week, when judgment pro confesso was entered against the Palmer & Singer Mfg. Co., of New York City, in United States District Court for the Southern District of New York. Suit against the latter was instituted at the same time that similar actions were brought against the Winton Motor Carriage Co., the Locomobile Co. of America and Maxwell-Briscoe, Inc., the Winton, Locomobile and Maxwell suits being taken care of by the Automobile Board of Trade while the Palmer & Singer action was conducted more or less independently.

Palmer & Singer failed to file an answer or demurrer within the specified time, and since then several extensions have been granted for the filing of an answer, but not for the entering of a demurrer. The last extension expired Saturday, July 13th, on which day Palmer & Singer's attorney filed what was termed a demurrer, and at the same time secured from Judge Lacombe an order requiring the Enterprize company to show cause why the time should not be extended to the October rule day of the court. The Enterprize attorneys opposed the motion, citing, among other things, the numerous extensions of time which had been granted and asked for a judgment pro confesso, which, in simpler language, is a judgment by default. Judge Hand granted the motion, and his decree has been entered on the court rec-

Digitized by Google

ords. The Dyer interests now will wait the expiration of a prescribed term of 30 days, when they will apply for an interlocutory decree and ask for the appointment of a master to take an accounting of the profits accruing to the Enterprize company from the Palmer & Singer Mfg. Co. Further intervention is possible, but if it is not successful a permanent injunction will be the next step.

Late last week the Enterprize Automobile Co. also secured a similar judgment against Albert Solvay in the United States District Court for the Eastern District of New York. Solvay, who is a liveryman operating two Darracq cars in Brooklyn, was charged with infringement of the two Dyer patents, but as he failed to present evidence in support of his answer and to appear at the final hearing, Justice Van Vechten Veeder ruled that the complainant's proof made out a prima facie case of infringement and granted the decree asked.

Simms Magneto Completes Reorganization.

After several months of planning, the reorganization of the Simms Magneto Co., of Bloomfield, N. J., at length has been effected, though all the officers of the new company, which will retain the name of the old one, have not yet been elected. C. G. Stoddard, whose former connection with the Dayton Motor Car Co. and present connection with the recently organized Edwards Motor Car Co., has served to bring his name into prominence, has been made president, F. R. Simms, who up to the time of the reorganization was president, having resigned that position. Simms remains a director, however; his associates are Edwards, A. A. Fisher, who is acting treasurer and who occupies a similar position with the Assets Realization Co., of New York, which company is financing the project, Campbell Carrington, who also is intimately connected with the affairs of the financing company, and H. M. Kilborn, who is vice-president of the National City Bank. The company has been reorganized with $1,750,000 capital stock, of which $1,000,000 is represented by the old stock of the company, all of which is common; the remaining $750,000 represents the new issue, of which $500,000 is preferred. All the new preferred has been subscribed, and after the proceeds have been applied to paying the outstanding debts of the company, it is expected that there will be at least $350,000 remaining with which to push production, which will be inaugurated immediately.

Yoeman Becomes Ames's General Manager.

George W. Yoeman, sales manager of the Continental Motor Mfg. Co., of Muskegon and Detroit, Mich., has resigned that position to become vice-president and general manager of the Ames Motor Car Co., of Owensboro, Ky. The Ames company is the outgrowth of the Ames carriage business, which has been conducted in the Kentucky city for the past thirty years. The Ames 1913 model will list at $1,585.

OBJECTS TO SUMMER TRUCK SHOW

New York Organization Opposed to N. A. A. M. Proposal—But Wants National Body to Further Parades.

Although the proposal to hold a monster Summer commercial vehicle show, either in addition to or to take the place of the usual Winter show, has been seriously considered by the National Association of Automobile Manufacturers, the matter having been referred to the show and commercial vehicle committees at the last meeting of the executive committee of that body, in order that the opinion of manufacturers and dealers with regard to the project might be ascertained, it is unlikely that anything will come of it, if the sentiment expressed at the last meeting of the Motor Truck Club of New York City can be taken as an indication.

The question of the advisability of staging such a show was the principal point that was discussed at the meeting, and the club finally went on record as opposed to the holding of any other than the national shows which are held in Madison Square Garden and Grand Central Palace each Winter, the concensus of opinion being to the effect that such a project would be detrimental rather than beneficial to the industry. Another suggestion which came in for more or less discussion was the advisability of holding a local truck show somewhere on the streets of New York, but it was pointed out that there would be difficulty in obtaining the necessary police permits, etc. Nevertheless, a committee finally was appointed to confer on the feasibility of holding a local commercial vehicle show in an arena of some sort in the vicinity of New York, the event to take place probably next Spring.

The matter of the annual parade also was much discussed, and it was voted to recommend to the N. A. A. M. that an effort be made to hold truck parades on some designated day simultaneously in the various large cities, the belief being that such a unified and concentrated showing would cause a great deal more enthusiasm and talk than a single parade in a single city. In connection with such parades, it was proposed, tentatively, that they might be arranged to be brought to a close with a general parking of the vehicles in line in order to effect a co-operative display.

Southern Railroads May Increase Rates.

If E. M. Goodwin, the representative of the L. & N. Railroad, had his way, there would be no carload rates on tires or anything else. Goodwin said so at the annual meeting of the Southern Railway Association in Atlantic City, at which J. S. Marvin, traffic manager of the National Association of Automobile Manufacturers was present. Goodwin's remark was brought out by Marvin's plea for the establishment of a carload rate on tires, which at present does not exist. The Southern Railway Association, which controls traffic south of the Ohio River and east of the Mississippi, is bent on increasing the rate on automobiles, in carload lots at least. At its meeting in Atlantic City, it considered a proposal to reduce the minimum weight for automobiles in carload lots from 10,000 to 5,000 pounds, and as they bear a double first class rate this change would serve to double the rate. Marvin made a strong protest but no decision has yet been reached.

Many More Assembling Plants for Ford.

In addition to the service stations and assembling plants which the Ford Motor Co., of Detroit, already maintains in New York City—to which four stories are to be added—and Kansas City, and in addition to those which, as already is known, are to be located in St. Louis, San Francisco, Los Angeles, Portland and Seattle, it transpires that it is the Ford intention to locate similar establishments in Boston, Philadelphia, Chicago, Minneapolis, Denver and Memphis, the smallest of which, incidentally, will be larger than was the entire Ford factory eight years ago. James Couzens, secretary and treasurer of the Ford company, indicates that the establishment of these assembling plants will reach unusual proportions and that there will be 20 or 30 of them when the Ford plans are carried to completion.

Mosler Accuses Wooster of Price-Cutting.

Claiming that William Wooster, trading under the high-sounding name and style of Automobile Surplus Stock Syndicate and having three places of business in New York City, infringed the Mosler patents under which Spit-Fire spark plugs are made, by selling them at less than a stipulated price, A. R. Mosler & Co., of New York City, brought suit against him late last week in United States District Court for the Southern District of New York. The complainant asks an order restraining Wooster from infringing the patents, Nos. 698,042 and 738,831, and from selling or otherwise handling Mosler spark plugs.

Nash Now a General Motors Official.

C. W. Nash, for the past two years vice-president and general manager of the Buick Motor Co., of Flint, Mich., has been appointed vice-president of the General Motors Co. to fill the vacancy caused by the resignation of W. J. Mead, who recently assumed the presidency of the Amplex Motor Car Co., of Mishawaka, Ind. As the Buick company is one of the subsidiaries of the General Motors Co., Nash, despite his new honors, still will remain the directing head of the Buick plant.

Cole Increases Capital to $500,000.

The Cole Motor Car Co., of Indianapolis, has increased its capital stock to $500,000. Its previous capitalization was $300,000.

CLIMAX IN MAIS TRUCK AFFAIRS

Enforcement of Mechanics' Lien Leads to Appointment of Receiver—Plant Probably Will Be Offered for Sale.

Trouble which has pursued it for several months culminated last week in the appointment of Franklin Vonnegut as receiver for the Mais Motor Truck Co., of Indianapolis. The receivership grew out of the application of Edward King, a contractor, who asked also that the Mais plant be sold to satisfy his mechanic's lien of $2,250. The court indicated that it probably would grant this application and order the plant sold within 30 days. King performed some building operations for the Mais company to the value of $5,050, of which but $2,800 has been paid.

At the time the receiver was appointed several creditors sought to have Frank D. Stalnaker, president of the Indiana National Bank, named for that position, but objections were lodged, as the bank is one of the creditors of the Mais company.

In November last Harold S. Block, a stockholder, made charges against the company and asked the court to appoint a receiver, but the action was not pressed. It was quite generally known, however, that the Mais company was not sailing on smooth water, but it was understood that reorganization was in progress, and until two weeks ago it was believed that receivership proceedings would be avoided. At that time, Will H. Brown, president of the company, interested capital in Peru, Ind., and in that city organized the Brown Commercial Car Co., which will manufacture a light truck, which action on his part was taken to foreshadow a climax in Mais affairs.

Former Warren Men Form New Company.

J. G. Bayerline, former general manager of the Warren Motor Co., of Detroit, and T. A. Bollinger, who was factory manager for the same company, practically have completed the organization of a $300,000 company which will establish itself in Detroit and produce a 30-horsepower touring car, which will be listed at $1,050. J. G. Seigfried and W. L. Daly, who also were connected with the Warren company, are associated with Bayerline and Bollinger in the new enterprise, in which Toledo, Chicago, Detroit and California capital is interested. The Californian who is interested and who will be sales manager of the new company, last year marketed 300 cars on the Pacific Coast, in which territory he has 148 sub-agents. Although the name of the company has not yet been chosen, plans are so far advanced that a factory in Detroit already has been secured and orders have been placed for material for 2,500 cars, the first of which already is operating on the streets of Detroit. It is an attractive model, having four cylinders, 3¼ x 5 inch, Warner transmission, multiple disc clutch, full floating rear axle, Bosch magneto, Stromberg carburetter and 110-inch wheelbase.

Westinghouse Gets $104,000 from Bergdoll.

Judgment for $104,000 was entered on Thursday last, 18th inst., in the Common Pleas Court No. 4, at Philadelphia, in favor of the Westinghouse Machine Co. against the Louis J. Bergdoll Motor Co., of Philadelphia, the judgment growing out of a suit involving a contract for 1,000 gasolene motors which the Bergdoll company had placed with the Westinghouse corporation. The contract, executed May 15, 1910, called for the delivery of 100 motors a month, the Bergdoll company agreeing to pay $210,000 in specified installments. When 550 motors had been delivered, a disagreement arose which caused the Westinghouse company to call the law to its aid. The Bergdoll company set up a counter claim for damages, alleging that the motors had not been delivered according to specifications, but the court ruled that the contention was without merit and gave judgment to the Westinghouse company for the full amount.

Morgan Truck Acquires New President.

Charles B. Foster, for the past ten years president of the Foster & Richardson Bedstead Co., of Westboro, Mass., has acquired an interest in the Morgan Motor Truck Co., of Worcester, Mass., of which he will assume the presidency on August 1st. Although one of the pioneers in the commercial vehicle industry, the Morgan company has had a long succession of ups and downs and several times has undergone reorganization. Foster's entry into its affairs marks a somewhat similar stage in its existence.

Federal Court Names DeTamble Receiver.

Supplementing two petitions in bankruptcy which already are pending in state courts, three creditors last week filed a similar petition in the Federal court of Indiana against the DeTamble Motors Co., of Anderson, Ind. They charge that while insolvent the company has made preferential payments to certain creditors. Their petition was granted, J. C. Teegarden, of Anderson, being named receiver.

Mutual Taxameter Ceases its Ticking.

Alleging preferential payments, Ducasse & Co., of New York, and two other creditors whose claims amount to $5,818.14, on Monday last, 22nd inst., filed a petition in bankruptcy against the Mutual Taxameter Cab Co., of 249 West 80th street, New York. Its liabilities are said to equal that amount, but its assets are not given.

Kinsey Increases Capital to $3,000,000.

The Kinsey Mfg. Co., of Toledo, O., which is one of the John N. Willys group, has trebled its capitalization—from $1,000,000 to $3,000,000.

KLAXON IS DENIED AN INJUNCTION

In Denying it, Federal Court Expresses Opinion of Conditional Licenses—Decision Favors Rhode Island Jobber.

Declaring that conditional licenses, such as attach to the sale of Klaxon horns, are "questionable" and are "likely to impose upon the purchaser catchy bargain conditions which he does not appreciate," Justice Brown, sitting in the United States District Court in Providence, R. I., on Tuesday last, 23d inst., denied the application of the Lovell-McConnell Mfg. Co., of Newark, N. J., for an injunction restraining the Waite Auto Supply Co., of Providence, from the further sale of Klaxon horns and also the sale of Newtone horns, to the handling of which by the Waite company the institution of the proceedings was due.

The Lovell-McConnell license, which is attached to each Klaxon horn, carries with it the recognition by the purchaser of the validity of the Klaxon patents, violation of which, in any form, is considered sufficient to render the purchaser "objectionable." As the Newtone horn is alleged to infringe the Klaxon patent, the Lovell-McConnell company, following its procedure in other courts, sought to restrain the Waite company from handling not only the Klaxon product but the Newtone horns also, which application, if granted, would serve to render valueless the horns which the Waite company has on hand. Judge Brown stated, however, that such forfeitures "are not favored by equity and will not be aided on merely technical ground." He also held that the "complainants have failed to show that they are likely to suffer such irreparable injury pending final hearing as to require a preliminary injunction."

While several similar actions have been tried in other courts, the proceedings before Judge Brown reached further and went into phases of the situation which had not previously entered into argument. His decision, therefore, had been awaited with unusual interest as tending to clarify the confused situation caused by the extended litigation in which the manufacturers of the Klaxon and Newtone horns are engaged. Judge Brow's decision denying the injunction is as follows:

"This is a petition for preliminary injunction against alleged infringement of Letters Patent Nos. 923,048, 923,049 and 923,122, to Hutchison, May 29, 1909. The patents relate to mechanically actuated diaphragm horns or alarms. Certain of these horns were sold to the defendant with a label attached thereto, to the effect that they were received and sold only under and subject to certain conditions.

"The bill alleges that by purchase, by acceptance and by resale, the defendant is a purchaser who has specifically acknowl-

Digitized by Google

edged the validity of said patents and that by reason of the premises the defendant is now estopped to deny the validity of said patents.

"The bill also alleges that the defendant also signed a supplementary selling license wherein it acknowledged its familiarity with the complainants' system of selling horns under conditional licenses. It is charged that the defendant has advertised and sold and threatens to continue to advertise and sell automobile horns designated as the Newtone horn, made by another manufacturer, but embodying said inventions, in infringement of the rights of the complainants.

"The bill prays an injunction against the manufacture, use or sale of the complainants' horns, known as Klaxon and Klaxonet, of the kind purchased by the defendant, and also for an injunction against the use or sale of the Newtone horn, or any similar horn, at the same time that it uses advertises or sells the horns manufactured by the complainants, and also against purchasing complainants' horns without special written permission of the complainants.

"Under ordinary rules a preliminary injunction against the sale of Newtone horns would be denied upon the complainants' showing. The proposition that the defendant has estopped itself from contesting the validity of the patents in a suit to enjoin the sale of the products of other manufacturers is very doubtful.

"The condition as to the acknowledgement of the validity of the patents seems rather a limitation of rights acquired in the use of a particular instrument than a general agreement with the vendor. Even should it be held that the relation established by purchase with knowledge of such conditions, is strictly constructural, a point that requires further consideration, there is good ground for thinking that such contract must be confined to specific subject matter for sale.

"It is a peculiarity of this form of license that by its terms the instrument itself is licensed. The proposition that the purchaser of one of these instruments, with knowledge of the conditions, has thereby agreed to acknowledge the validity of the patents, in suit for all purposes, and in respect to other articles, is questionable for several reasons.

"The acceptance of this proposition would be likely to impose upon a purchaser by a catchy bargain condition, which he did not appreciate. Upon motion for a preliminary injunction against the use of Newtone horns, I am of the opinion that the complainants' case is not aided by the contention that the defendant is estopped or has agreed not to contest the validity of the patents in respect thereto.

"The case presents also a further question as to whether equity should lend its aid to enforce the provisions in respect to a single instrument and shall revoke all rights as to other instruments in the violator's possession. Forfeitures of this character are not favored by equity and will not be aided on merely technical grounds.

"Furthermore the complainants fail to show that in respect to sales of Klaxon or Klaxonet horns by the defendants, the complainants are likely to suffer such irreparable injury pending a final hearing as to require a preliminary injunction. The petition for a preliminary injunction is denied."

Changes Among Prominent Tradesmen.

Charles S. McCarthy has resigned the position of superintendent of the Wagner Mfg. Co., of Toledo, O. After a short vacation, he expects to return to that city, where he again will engage in business.

A. H. Brown, manager of the Studebaker Corporation's Spokane (Wash.) branch, has been promoted to the post of northwestern sales manager. He will continue to make his headquarters in Spokane.

J. G. Satterthwaite has been appointed manager of the Philadelphia branch of the Whiting Motor Co., which recently took over the Mercer branch in that city. Previously, Satterthwaite was manager of the Trenton (N. J.) branch of the Stoddard-Dayton company.

Benjamin Geddis and D. C. Richardson, both of whom have been connected with the Warren Motor Car Co.'s Detroit branch, have resigned, the former to manage the Warren car department of the Forbes Motor Co., of Pittsburg, Pa., and Richardson to become sales manager for Forbes Motor Co., of Pittsburgh, Pa., and ton, D. C., which also handles the Warren car.

L. C. Smith, who has been serving on the General Motors advertising staff in Detroit, has been appointed advertising manager for the Olds Motor Works, with headquarters at the factory in Lansing, Mich. He succeeds to the vacancy caused by the resignation of George L. East, who has been appointed advertising manager for the Amplex Motor Car Co., of Mishawaka, Ind.

Edward H. Habersham, who for some time has been doing confidential work for the Studebaker Corporation's sales department, has been appointed manager of that company's Washington (D. C.) branch. He succeeds Walter C. Vliet, who is to be promoted to an important assignment in the Studebaker service in the West. Incidentally, the Washington branch, which heretofore has been operated under the title E-M-F Washington Co., hereafter will be conducted in the name of the Studebaker Corporation itself.

Cancels Option, Universal Will Expand.

When the Metzger-Flanders amalgamation was steaming hot two months ago, and when the prospect of a merger of considerable magnitude appeared probable, it was freely stated that the Universal Motor Truck Co., of Detroit, was a party to the negotiations, which reports, however, were several times denied. The truth came out last week, however, at a meeting of the board of directors of the Universal company, when it was made known that an option on the Universal plant had been granted to Walter E. Flanders and his associates and that it had been formally canceled. It is understood that the cancelation last week did nothing to further the good feeling existing between the several parties to the negotiations.

Having decided to go it alone, the Universal company is preparing to become a million dollar corporation and is laying plans for the erection of what is designed to prove the largest exclusive truck producing plant in the world. It will make a specialty of a one-ton worm driven model, which has been developed during the past year. Fred K. Parke, at one time a vice-president and confidential member of the Studebaker staff and an intimate associate of Walter E. Flanders, will remain vice-president and general manager of the Universal Motor Truck Co., the control of which rests with George Uhlein, who is identified with the Schlitz brewery interests in Milwaukee, and W. S. J. Kopmeier, of Detroit, both of whom are also stockholders in the Flanders Mfg. Co.

Van-L Truck is Declared Bankrupt.

The Van-L Commercial Car Co., of Grand Rapids, Mich., has been formally adjudicated a bankrupt by the Federal court in that city, Kirk E. Wicks being appointed referee in bankruptcy. The adjudication follows a petition filed late last month by stockholders, asking the appointment of a receiver on the grounds that the company transferred or attempted to transfer its assets to the Commercial Service Truck Co. in fraud of the Van-L creditors and stockholders, it being alleged that the Commercial company was organized to take over the Van-L.

American Completes Factory Enlargement.

Due to the completion of an addition to its plant in Indianapolis, the American Motors Co. now claims to possess the largest automobile factory in that city. The new building is an imposing structure of three stories, 85 x 100 feet, and provides about 35,000 square feet of floor space. The company already is equipping the plant, the new machinery being of the most modern design. One piece that is being installed is a 36-ton hydraulic press which is to be used for shaping the American underslung bodies and sheet metal work.

Haas Tire Seal Admits it is "Broke."

The C. W. Haas Tire Seal Co., which maintains an office and garage at 800 Hamilton street, Peoria, Ill., has filed a petition in bankruptcy. Its liabilities amount to $9,074 and its assets to $10,251.59. The latter comprise open accounts, $6,945.77; patents, $1,000; stock, $2,300; and cash, $582.

THE WEEK'S INCORPORATIONS

Kansas City, Mo.—Place Garage Co., under Missouri laws, with $5,000 capital; to operate a garage.

Coldwater, Mich. — Coldwater Garage, under Michigan laws, with $3,000 capital; to operate a garage.

Dover, Del.—Keystone Automobile Exchange, Inc., under Delaware laws, with $100,000 capital; to deal in motor cars.

Hager, J. W. Hager, A. Z. Hager, R. T. Pitman.

Buffalo, N. Y.—Mason B. Hatch, Inc., under New York laws, with $20,000 capital; to deal in motor cars. Corporators—Mason B. Hatch, Isabelle W. Hatch, John Chipman.

St. Louis, Mo.—Burns-Ramsden Motor Car Co., under Missouri laws, with $10,000 capital; to deal in motor cars. Corporators—Louis N. Burns, J. H. Ramsden, Harry C. Barker.

Des Moines, Ia.—Thermon Mfg. Co., under Iowa laws, with $10,000 capital; to manufacture motor devices. Corporators—K. N. MacDonald, W. P. Bair, W. A. Spurrier, Jr.

Des Moines, Ia.—No-Air Tire Filler Co., under Iowa laws, with $10,000 capital; to manufacture tire filler. Corporators—Edward Crawford, William Nutter, Lon H. Boydstron.

Cleveland, Ohio—Saunders Auto Supply Co., under Ohio laws, with $10,000 capital; to manufacture motor devices. Corporators—C. J. Robinson, S. W. Sparks, J. A. Blakley and others.

Chicago, Ill.—Chicago General Motorbus Co., under Illinois laws, with $1,000 capital; to operate a motor bus line. Corporators—Henry W. Berg, W. C. Norton, John Reckinger.

Indianapolis, Ind. — Janney Electric Starter Co., under Indiana laws, with $100,000 capital; to manufacture motor starters. Corporators—C. D. Janney, Russell Wilson, W. L. Taylor.

Terre Haute, Ind.—Little Wonder Light Co., under Indiana laws, with $10,000 capital; to manufacture lighting equipment. Corporators—Charles Van Slyke, C. P. Walker, H. R. Ihrie.

Burlington, Ia.—Hawkeye Motor Car Co., under Iowa laws, with $15,000 capital; to manufacture motor cars. Corporators—H. L. Madison, E. L. Horsford, L. H. Vahle and others.

West Allis, Wis.—West Allis Machinery and Auto Co., under Wisconsin laws, with $1,000 capital; to operate a machine shop Corporators—Joseph W. Moore, Frank Meyer, James McCue.

Pontiac, Mich.—Hemmeter Spark Gap Mfg. Co., under Michigan laws, with $6,000 capital; to manufacture spark gaps. Corporators—Henry C. Hemmeter, Cassius C. Van Wagoner, John Snyder.

New Brunswick, N. J.—Consolidated

BIRD'S-EYE VIEW OF LOCOMOBILE PLANT AT BRIDGEPORT, CONN., AFTER ITS ENLARGEMENT

With recent additions, the floor space is equivalent to more than eight acres, all parts of the Locomobile models now being manufactured on the premises.

Dover, Del.—Keystone Automobile Exchange, Inc., under Delaware laws, with $100,000 capital; to deal in motor cars.

Springfield, Ill.—Triumph Motor Car Co., a South Dakota Corporation, with $75,000 capital; admitted to do business in the State of Illinois.

St. Louis, Mo.—Model Auto and Sales Co., under Missouri laws, with $3,000 capital; to deal in motor cars. Corporators—Oscar Sonntag, Roy E. Stults, Otto F. Karbe.

East Orange, N. J.—Orange Garage, under New Jersey laws, with $20,000 capital; to operate a garage. Corporators—S. L. Gedney, Jr., J. D. Gedney, H. R. Picking.

Nashville, Tenn.—Hager Motor Car Co., under Tennessee laws, with $5,000 capital; to deal in motor cars. Corporators—L. S.

Digitized by Google

Auto Supply Co., under New Jersey laws, with $1,000,000 capital; to deal in motor car supplies. Corporators—B. F. Hardesty, Arthur V. Dennan, Samuel Ross.

Peru, Ind.—Brown Motor Truck Co., under Indiana laws, with $100,000 capital; to manufacture motor trucks. Corporators—William H. Brown, C. H. Wallerich, R. A. Edwards, R. H. Bouslog, Max Kraus.

Cincinnati, Ohio—Acme Motor and Delivery Co., under Ohio laws, with $15,000 capital; to operate a motor delivery. Corporators—William E. Minor, Fred K. Allen, Stuart B. Stutphin, David Wachman, Bradford Minor.

Cincinnati, Ohio—King Valveless Auto Whistle Co., under Ohio laws, with $25,000 capital; to manufacture motor car devices. Corporators—Delroy Fiffield, Orville C. Snyder, George H. Burrows, R. E. McMasters, C. J. Lowrie.

New York, N. Y.—Essenkay Sales Co., under New York laws, with $100,000 capital; to deal in tire fillers, etc. Corporators—Henry S. Young, 101 West 83rd street; Byron F. Abbott, 996 Simpson street; William C. Oliver, 425 West 42d street.

Brooklyn, N. Y.—E. Reinking Automobile Supply Co., under New York laws, with $5,000 capital; to deal in motor car supplies. Corporators—Emil Reinking, 376 Euclid avenue; John Lucht, 85 Hill street; Bernard Nienstedt, 207 Hemlock street.

New York, N. Y.—Fifty-second Street Auto Repair Co., under New York laws, with $2,000 capital; to repair motor cars. Corporators—Arthur Williams, Jr., 325 Amsterdam avenue; Harold Matzinger, Mount Vernon; Anna H. Darre, 930 St. Nicholas avenue.

New York, N. Y.—International Autolamp Mfg. Co., under New York laws, with $300,000 capital; to manufacture lamps, etc. Corporators—Hyman Agar, 821 Bergen street, Brooklyn; Nathan Agar, 25 Broad street; Thomas Cunningham, 155 Huntington street, Brooklyn.

Far Rockaway, N. Y.—Far Rockaway Motor Cab Co., under New York laws, with $25,000 capital; to operate a taxicab service. Corporators—Edwin Sommerich, 624 Broadway, New York City; Joseph L. Steinman, 10 East 33rd street; Arthur Behel, 37 West 26th street, New York City.

Changes of Capital and Name.

Toledo, Ohio—Toledo Motor Truck Co. from $95,000 to $150,000.

Cincinnati, Ohio—Hanauer Automobile Co. from $20,000 to $50,000.

Springfield, Ill.—Springfield Auto Sales Co. from $35,000 to $50,000.

Santa Barbara, Cal.—El Camino Real Motor Car Co., from $15,000 to $25,000.

Columbus, Ohio—Akron Rubber Motor and Machine Co. from $10,000 to $30,000.

Chicago, Ill.—Automobile Owners' Association from $100,000 to $50,000 and name changed to Service Mfg. Co.

KNIGHT-ARGYLL SUIT MOVES SLOWLY

Litigation Over Sleeve-Valve Rights In England Drags—Defense Asserts Engine as Patented Inoperable.

The litigation which was inaugurated last November, immediately after the appearance of the Argyll sleeve-valve engine at the Olympia show in London, was brought to a partial head last week, when for the first time the suit for alleged infringement of patents brought by the Knight & Kilbourne Patents Co. against the Argyll company of Edinburgh, Scotland, came up for a hearing, the action being heard by Justice Neville in No. 3 Chancery Court. By reason of the voluminous character of the evidence, which included several engines and working models, however, the case still rests with the court, no judgment having been rendered as yet.

When the suit was instituted by the Knight & Kilbourne company, infringement of two of the four claims in its patent No. 14,729, of 1905, were alleged, these claims being as follows:

"1. The herein-described improvements in an internal combustion motor comprising the cylinder and a member telescoped therewith, said member comprising a head and a valve seat, one internal and the other external to the cylinder, said member and cylinder being relatively movable and the cylinder having ports adapted to be covered and uncovered by said relative movement, and a piston in the cylinder, in combination with means for substantially as herein described imparting to one of the aforesaid telescoped parts a movement which is relative to the other aforesaid telescoped part and variable with relation to the movement of the piston for covering and uncovering the ports."

"4. The herein-described improvements in an internal combustion motor, combined, constructed, and arranged substantially in the manner and for the purpose set forth."

In the argument for the defense, the usual claim of anticipation was set up, and it was contended, therefore, that no infringement was possible. In addition, it was alleged that no useful result could be achieved by following the specifications of the patent, and a counter-claim for its revocation was entered. In substantiation of the claim that the engine as described in the patent specifications was inoperable, and even if materially altered would remain of no practical use, it was pointed out that when the valve motion was plotted, the exhaust valve opened on the compression stroke. In fact, it was around this particular feature that much of the controversy raged.

In summing up for the plaintiff, it was argued that the Argyll engine was substantially a copy of the Knight engine and was an infringement of the rights of the owners of the patent covering it. In denying the contention of anticipation set up by the defendant, it was alleged that not a single paper had been submitted which had definite bearing on the combination of mechanism and movements covered by the Knight patent. In addition, referring to the defendant's contention that the patent specifications covered an engine which could not possibly be made to operate as shown, it is alleged that the defendants "were attempting to cloud the real issue insomuch as they were alleging various points against and anent the said specification which were not directly related to its function, viewed purely as a specification, but could only hold water on the assumption that the drawings in the specification were intended as working drawings." This was denied, and it was pointed out that patent specifications were never intended to be working drawings, no single instance where they were held to be such ever having been cited.

Though it is almost a year since the first action in the case was taken, the Argyll company has shown no disposition to discontinue the production of its unique type of sleeve-valve engine. Instead, it has continued to manufacture it in considerable numbers, and they have been disposed of as fast as completed. In every case, however, an indemnity has been offered to purchasers who might have feared litigation.

White Electric System on all Models.

Although only the six-cylinder model in the White line, which is produced by The White Co., Cleveland, O., heretofore has been equipped with the electric lighting and engine starting system, which was developed especially for it, all the models hereafter will be equipped with it. These include, in addition to the "six," the two four-cylinder models, one rated at 30 horsepower and the other at 40 horsepower. Briefly, the system embraces a combined dynamo and generator, which is connected to the engine through the intermediary of a "silent" chain, a liberal sized storage battery and the necessary switches for controlling the lamps and the starter.

Haynes Takes Over San Francisco Agency.

The Haynes Automobile Co., of Kokomo, Ind., have taken over the Haynes Auto Sales Co., of San Francisco, and hereafter will operate the establishment at Van Ness avenue and Turk street as a factory branch. W. B. Cochran, who was president and general manager of the San Francisco company, will remain in charge of the branch.

England's Exports Still Exceed Imports.

For the six months ending with June, England's export of automobiles and parts attained a total of £1,618,887, as compared with £1,459,069 during the corresponding period of last year. During the same period the imports increased even more markedly—from £3,056,177 to £3,674,733.

Joseph Nagle is about to open a garage in Brookfield, Ill.

Joseph Haertl is about to open a garage in Fox Lake, Wis.

The Louser stables in Lebanon, Pa., are being converted into a garage.

F. A. Fridley of Redlands, Cal., has purchased the Orange Street Garage.

The Nampa Lumber Co., of Nampa, Id., is building a garage, 50 x 140 feet.

Dr. J. M. Willis is erecting a commercial vehicle garage in Williston, Fla.

J. O. Tanner is building a fireproof garage on Walnut street, Columbus, Tex.

A. W. Fiske, an attorney of Ridgefarm, Ill., is about to build a garage, 93 x 38 feet.

Bert Norton of Napa, Cal., is building a garage, 35 x 85 feet, on Randolph street, near First.

W. H. Dillon is about to enter the automobile delivery business in Excelsior Springs, Mo.

George E. Robbins has opened a garage in Tampa, Fla.; it is located at Tampa and Jackson streets.

Torke Bros. are erecting a brick garage at Plymouth, Wis. They will expend $30,000 on the structure.

Shadle & Shull, a Montpelier (Vt.) garage firm, has dissolved; R. M. Shadle purchased James Shull's interest.

O'Briant & Jones, of Durham, N. C., have taken over and will conduct the garage business of Mangum & Morris.

A garage on Gold street, Negaunee, Mich., owned by D. D. Smith, has been leased to the Negaunee Garage Co.

H. W. Vaughn and E. J. Lee, owners of the Century Garage, in Watsonville, Cal., have sold out to R. Neill and S. Redwine.

Jason Chandler and Harris Biedsoe of Kosse, Tex., have purchased the J. T. Pritchard Garage; they will continue the business.

Permission has been granted to H. McFarland, of Chicago, to build a garage at 526-530 South Canal street; it will cost $5,000.

H. W. Yeager, president of the Yeager Piano Co., of Hartford, Conn., has "gone into" automobiles; he has taken the Velie agency.

Elmont and Clarence E. Brooks, of Santa Rosa, Cal., have purchased the Turlock Garage; they will adopt the style Brooks Auto Co.

William Braithwaite is erecting a garage in Esmond, N. D. Also he will operate a stage service between that town and nearby localities.

A. Friedman & Sons Co., of Milwaukee, Wis., has secured permission to build a garage on Lisbon street, near 25th; its cost will be $9,000.

W. A. Platt, of Mt. View, Cal., has purchased the automobile part of the business of Leach & Higdon; he will assume charge of it August 1.

West Allis Machinery & Auto Co. is the style of a new organization in West Allis, Wis.; a garage will be operated at 686 73d avenue.

Henry Koch & Co. of Newark, N. J., have accepted plans for a garage, 64 x 89 feet, to be built at 32-34 Wickiffe street; its cost will be $6,000.

Under the style Miller Motor Car Co., Hardie & Gillette, of Chicago, Ill., have opened up at 1806 Michigan avenue; they will handle the Miller car.

C. A. Burton of Findlay, O., has purchased the Main Garage at 300 North Main street from George Hale; Burton personally will conduct the business.

The Bournonville Realty Co. of 250 West 64th street, New York City, has secured permission to erect a two-story garage, 75 x 95 feet; it will cost $33,000.

F. M. Prince is about to erect a two-story steel and concrete garage at 27 Groveland terrace, Minneapolis, Minn. It will represent an expenditure of $10,000

Hannaford Barr and George Stilphen have formed a co-partnership in Sanford, Me., and will operate a garage on Mechanic street; the firm style is Maine Auto Co.

J. E. Granger of Long Beach, Cal., has leased the Central Garage, opposite the City Hall; he will handle the Brush and Detroiter cars and a line of accessories.

W. V. Caldwell and H. B. Bailey of Los Angeles, Cal., are erecting a white glazed brick garage at Newlin and West Philadelphia avenues; its cost will be $10,000.

A community garage with individual booths for motor car owners is to be erected at 821 Quincy street, Topeka, Kan. J. S. Warner, a dealer, is sponsor for the scheme.

Mrs. C. G. Castruccia, of Los Angeles, Cal., has been granted authority to build a garage at 2438 South Grand street; it will represent an expenditure of $7,410, according to plans.

H. H. Quine, of Denver, Col., has let the contract for a garage, 50 x 185 feet, to be located on Broadway between Fourth and Fifth avenues; it will represent an expenditure of $12,000.

Permission has been granted the House and Home Realty Co. of St. Paul, Minn., to build a garage, 60 x 150 feet, at 237 West Ninth street; the plans call for an expenditure of $30,000.

Under the firm style Up-to-date Garage, Ernest Wright has opened up at Chestnut and Ocean avenues, Long Beach, Cal. Wright has the agencies for the King car and U. S. Motor trucks.

M. J. Osborn, owner of a garage at 15 East 9th street, St. Paul, Minn., has purchased the garage of the Western Automobile Co. at 338 Cedar street; he will operate both establishments.

Replacing a stable which was destroyed by fire, the Pavilion Hotel, Montpelier, Vt., is about to build a garage; it will be of three stories and will be equipped with power elevator and other modern appliances.

H. F. Sundin, formerly a traveling representative of the National Motor Vehicle Co., of Indianapolis, Ind., has been made distributer for that company in Kansas City, Mo. He will have salesrooms on Grand avenue.

Burson & Fowler, operators of the Mission Garage in Santa Paula, Cal., have sold out to J. Standlee; Burson, however, will retain an office in the garage and continue as agent for E-M-F, Flanders and National cars.

Theodore H. Bower of Providence, R. I., has purchased an interest in the American Supply Co., of Tampa, Fla., and arrangements are being made for the improvement of the property; the concern carries Lambert cars and trucks.

Under the style Service Auto Co. four young men of St. Paul, Minn., have entered the garage field with quarters at 199 West Fifth street; the quartet consists of Benjamin F. Kartak, Dean Laroche, LaRoy Ensley and Joseph Tighe.

Miss Mabel Pitt of Des Moines, Ia., has sold her interest in the Pitt-Matthews Carriage and Auto Co. to Edwin V. Matthews and Richard G. Priebe; they will continue the business, having amended the articles or incorporation to eliminate the name of Pitt from the firm title.

Arch Kirkwood, a blacksmith, at 10 North Broadway, Pittsburg, Kan., is branching out into the garage field; he is building an addition to his shop and will have associated with him in business Geo. H. Bailey, formerly an employe in the Alexander Garage, in the same town.

The Jones Auto Co., of Oakland, Cal., which previously handled Regal automobiles in connection with accessories, has discontinued the sale of cars and hereafter will confine itself to the accessory jobbing trade. The two stores which the Jones

Digitized by Google

company previously maintained have been thrown into one and the company now claims to be one of the largest supply houses in its vicinity.

The Little Motor Car Co., of Flint, Mich., has established a branch in Indianapolis, at 338 North Delaware street. It is in charge of H. C. McVey, who previously was identified with the Buick branch in the same city.

A new Apperson agency has been formed in Omaha, Neb., consisting of J. H. De Long and Hans P. Neble; the latter's two sons will be connected with the business. For the present the old Apperson store at Eleventh and Farnam streets will be retained.

On the application of the Everitt Motor Car Co., of Detroit—formerly the Metzger Motor Car Co.—the Metzger Motor Car Co., of Denver, Colo., has been thrown into bankruptcy. Save for the relation of manufacturer and dealer, there was no connection between the two companies, although they bore the same name.

C. K. Eagle and J. C. Brown, members of J. H. & C. K. Eagle, a Shamokin (Pa.) silk manufacturing concern, and owners of the Edgewood Garage in that town, have purchased the business of the Shamokin Automobile Co. The latter's establishment is 160 x 60 feet and is well equipped, and henceforth will be styled Edgewood Garage, the title of the purchasers' first establishment. L. D. Kamp is manager of the business.

Landlord Acts Against Wishart-Dayton.

Because of alleged failure to pay the June and July rent on the premises at 318 West 48th street, New York City, judgment was taken this week against the Wishart-Dayton Auto Truck Co., by A. W. H. Nichols for $605.81, and has been entered in the New York county clerk's office. The company maintains an office at 501 Fifth avenue but rented the 48th street building for storage or service purposes, it is said.

Two More Abandon Yearly Model Policy.

Two more conspicuous companies have abandoned the "yearly model" policy—the Pierce-Arrow Motor Car Co., of Buffalo, N. Y., and The White Co., of Cleveland, O. Their cars no longer will be designated by years, such mechanical changes as are deemed necessary being incorporated whenever they are found advisable and without concentrating such action at the close of the seasons.

Making Room for More Michigan Cars.

To relieve the pressure on its busy plant, and to permit of an increased output of Michigan cars, the Michigan Buggy Co. last week broke ground for an enlargement of its factory in Kalamazoo, Mich. The enlargement will comprise a four-story steel and concrete building, which will afford 50,000 square feet of additional floor space.

VAN WAGONER PATENT LOCATED

Claimed to Control Shaft Drive for Electrics and Litigation is Likely—Involved in Buffalo Merger.

Some three months ago, when the Buffalo Electric Vehicle Co. was formed and took over the Babcock Electric Carriage Co. and the Clark Motor Co., among other properties, the attractiveness of the Clark company was not wholly clear. It had produced few cars, and had cut absolutely no figure in the industry; but, as the Motor World pointed out at the time, it was possessed of the Van Wagoner patent which, as was stated, was supposed to have a considerable bearing on the electric vehicle industry, but efforts to learn more about the patent proved unavailing. For some reason, none of those interested were willing to impart information. Since then, however, the patent has been located and the search for it has served to bring out the statement that back of the Buffalo Electric Vehicle Co. stands the powerful General Electric Co., in whose control the Van Wagoner patent is alleged to repose. The statement lacks verification, however, all efforts in that direction having failed of their purpose.

The Van Wagoner patent itself proves to be an important one—so important that at one time other interests sought to obtain control of it, but inability to locate its owners put an end to the endeavor. When or how the Clark Motor Co., of Buffalo, secured it is not known, but as the patent is believed to control the shaft drive as it applies to electric vehicles, that it is likely to be brought to bear at any time is not denied. The patent is No. 671,036 and was granted April 2, 1901, to William Van Wagoner, by whom it was assigned to the Century Motor Vehicle Co., of that city, which produced steam cars but which long since gave up the ghost. It specifically covers a "drive mechanism for automobiles in which the power is applied to the axles of the rear wheels by a longitudinal shaft," and is made up of seven claims, as follows:

1. The combination of the carriage body, the running gear, a longitudinal shaft for driving the rear wheels, a motor frame connected with the front portion of said shaft, and a transverse pivotal connection by which the motor frame is connected to the carriage body, substantially as described.

2. The combination of the carriage body, the running gear, a longitudinal shaft for driving the rear wheels, a motor frame connected with the front portion of said shaft, and hangers which are connected with the car body by transverse pivots and to which the motor frame is connected by transverse pivots, substantially as described.

3. The combination of the carriage body, the running gear, a longitudinal shaft for driving the rear wheels, a motor frame connected with the front portion of said driving shaft by a longitudinally-movable connection, with a transverse pivotal connection by which said motor frame is connected with said carriage body, substantially as described.

4. The combination of the carriage body, the running gear, a longitudinal driving shaft, a casing for the same journaled at its rear end transversely on the rear portion of the running gear, a motor frame having a longitudinally-movable connection with the front end of said shaft-casing, and a transverse pivotal connection by which said motor frame is connected with said carriage body, substantially as described.

5. The combination of the carriage body, the running gear, a longitudinal driving shaft for driving the rear wheels, a motor frame connected with the body by a transverse pivotal connection, and a longitudinally-sliding and longitudinally-rotary connection by which the motor frame is connected with the front portion of the said shaft, substantially as described.

6. The combination of the carriage body, the running gear, a longitudinal driving shaft, a tubular casing for the same journaled at its rear end transversely on the rear portion of the running gear and provided with bearings at its rear and front ends, in which said shaft is journaled, a motor frame having a longitudinal bearing in which the front portion of said shaft-casing is capable of longitudinal and rotary movement, and a transverse pivotal connection by which the motor frame is connected with the carriage body, substantially as described.

7. The combination of the carriage body, the running gear, a longitudinal driving shaft provided with a gear wheel, a motor shaft provided with a driving pinion which meshes with said wheel, a gear casing enclosing said wheel and pinion, a tubular shaft casing extending from said gear-wheel casing rearwardly and journaled transversely on the rear portion of the running gear, a tubular shaft casing extending from said gear casing forwardly, a motor frame provided with a longitudinal bearing in which the front portion of said shaft casing is capable of longitudinal and rotary movement, and a transverse pivotal connection by which the motor frame is connected with the carriage body, substantially as described.

To Make Munsing Three-Wheel Tractors.

The Munsing Tractor Co., which has been incorporated under New York laws with $600,000 capital stock, has in view the production of the Munsing tractor, a three-wheeled vehicle which is specially designed to convert horse trucks into motor vehicles. It is characterized by a transmission having three speeds forward and three reverses, the reverse "being obtained on any forward or backward speed without using a hand lever and merely by pressing or releasing a pedal," the change of speed, according to the description, being "accomplished by simple clutches instead of sliding gears." Basil Magor, of 30 Church street, New York, who also is interested in the Magor Car Co., which purposes manufacturing railway cars, is the best known of the incorporators of the Munsing Tractor Co. Inquirers at Magor's office, however, are referred to M. E. Grey, an engineer located at 120 Liberty street, and Grey declares that he is so busy at this time that he cannot give any intimate information concerning the Munsing tractor or the Munsing company.

NEW YORK, JULY 25, 1912

UNSETTLING PRICES OF PATENTED PRODUCTIONS.

Having failed to induce his own committee to report his voluminous bill designed to revolutionize the patent system in vogue in this country, it is easy to understand that Chairman Oldfield, of the House Committee on Patents, should not be wholly happy. It is as easy to understand that to relieve at least a part of his unhappiness his colleagues should approve a much shorter and very much modified measure, particularly as the days of the present Congress are numbered, which makes appear that even the compromise bill will not progress to the enactment stage. It is more difficult to understand, however, why even a compromise measure should seek to make it unlawful for a manufacturer to fix the retail price of a patented article.

There is some justification for the Oldfield proposal prohibiting manufacturers from specifying particular materials or appliances in the operation of their patented devices. While the arguments against such a provision do not lack strength, the practice of so extending the scope of a patent that it may be made to include any or many unpatented materials or devices is fraught with far-reaching consequences, and though it is claimed to automatically regulate itself, it is, nevertheless, capable of serious abuse. There is justification also for the Oldfield proposal requiring owners of patents which shall have remained unworked for a period of five years to issue licenses to all applicants; for a dead patent is either valueless or is left unworked for ulterior purposes. But any effort to prevent the manufacturer of a patented article from fixing the price of his production is repugnant and is in the nature of robbing the patentee of the fruits of his ingenuity. It would serve considerably to upset the commercial practices of the world and would set many industries at sixes and sevens, for, despite arguments to the contrary, and when they are not in the nature of such general agreements as the law properly defines to be in restraint of trade, fixed retail prices for very many articles constitute a stabilizing and equalizing influence, the worth of which cannot be estimated. When values are unsettled chaos yawns.

While the same does not hold true of raw materials, there is no manufactured article covered by patents which is so essential to individual welfare that it must be purchased regardless of price, and there is no law or other force which compels any person to purchase any article, the price of which does not please him. For a period of seventeen years, the Federal law allows a patentee the right to do what he will with the fruit of his ingenuity, and while it may be wise for Congress to seek to prevent abuses which have grown up there is small wisdom in lessening the premium which the present law places on ingenuity; and the greatest of these premiums is the right to fix the price of the product of such ingenuity. It should remain the right and privilege of every patentee.

THROWING LIGHT ON THE GASOLENE UPLIFT.

Out of one of the mouthpieces of Wall Street has issued the statement that "fortunately," the Standard Oil Co., previous to the astounding rise in the price of its products, had in storage more than one hundred million barrels of crude oil, and "naturally is receiving great benefits from the higher prices," which, the Wall Street oracle fails to state, are of Standard Oil's own making and are wholly without precedent. It does state, however, that the current year is more than likely to prove one of the best in the history of the big corporation and also takes occasion to remark that the shares of the Standard Oil of New Jersey have appreciated to the value of more than $350,000,000 since the trust went through the motions of dissolving late last year; which is not at all strange, when it is recalled that the price of gasolene alone has been increased more than 75 per cent. in the course of six months.

The fact that the company was so farsighted as to be able to store more than one hundred million barrels of crude petroleum, seems to suggest the hiding place of those elusive sprites, Supply and Demand, who so regularly have been called to the assistance of Standard Oil since its prices started on their skyrocket career. While only the brave will dare fancy that the Standard Oil would be guilty of attempting to corner any considerable portion of the country's product, the wisdom and ability to store such a considerable portion of the country's production will strengthen the belief of many unknowing persons that the increase in price is largely of an artificial nature and that the automobile interests, among others, are merely being made to pay some fiddler, or fiddlers.

Why so many persons, not excepting some of those who manufacture the devices, will persist in applying the term "self-starter" to engine starters is one of the things past finding out. It is self-evident that the application is incorrect, and in the interests of proper terminology it would seem as easy to call an engine starter an engine starter as anything else. So-called "self-starters" do not start themselves, and that is not their purpose. They are designed to start engines.

BENNETT ON HOT WEATHER WORK

Declares Summer the Season That Brings Out Real Salesmanship—Directions in Which to Expend Effort.

"This is the time of year that tests the qualities of a salesman," says George W. Bennett, vice-president of the Willys-Overland Co. "The salesman who is made of wax and melts with the heat and whose chief occupation consists of reading trade papers and who fans himself in the office shade and works only in cool weather is not made of the right stuff to sell motor cars.

"In these days of keen competition the salesman who does not work every minute will never succeed in anything. The hot summer months are the best season of the year for a salesman to get himself together, take account of stock and round up prospective buyers. A salesman who works with a vengeance through the summer should have his prospective buyer's notebook filled with names by the time the new models are announced.

"This is the right time for a city salesman to canvass his owners and ascertain how their cars are standing up, when they will be ready to take the new model, find a purchaser for the old car, get his customers' orders in to insure early delivery and see that the owner is being cared for in general.

"Many a sale is made by being 'Johnny-on-the-Job' during the hot season, and incidentally it means an increase in commissions and eventually promotion. I had rather have one man who can wade through his perspiration and make sales than fifty whose main thought in summer is the consumption of gin fizzes and a plunge in the surf."

Oldfield Drafts Compromise Patent Bill.

Although he has abandoned hope for his bill, which sought to revolutionize the patent system of this country, Congressman Oldfield of the House Committee on Patents finally has induced his committee to report favorably a compromise measure which embodies these three principal and drastic provisions:

Making it unlawful for manufacturers of a patented article to fix the price at which it is to be sold to the consumer by the retail merchants.

Prohibiting manufacturers from requiring the use of specified materials in the operation of patented devices.

Requiring patentees to issue licenses to applicants for the manufacture of any article covered by patents which shall not have been "worked" for a period of five years.

Even the favorable report of the Committee on Patents, however, does not assure the passage of the new measure, but Mr. Oldfield hopes to bring sufficient pressure on the Committee on Rules to induce it to place his bill on the calendar for disposition before the adjournment of congress.

Making the Repair Shop Attractive.

'Way down South in New Orleans, the Chalmers Motor Car Co. of Louisiana has found a way of making even a repair shop attractive. The attraction consists of Miss "Jack" Gray, aged 18, who is one of the company's "repairmen." She has been employed in the Louisiana Chalmers service department as a mechanic's helper for some three months, and, although she

MISS "JACK" GRAY—MECHANIC'S HELPER

wears "pants" she is nevertheless attractive, as the accompanying photograph serves to show. Manager Cummings, of the Chalmers Motor Co., adds that "she is as capable as a man in a similar position. What her idea is in learning the business we do not know," adds Cummings, "but she is enthusiastic about her work and seems to enjoy it."

Willys Details Output of Overlands.

For the first time, so far as known, one of the prominent manufacturers identified with the automobile industry has made public a detailed statement of his output. He is John N. Willys, president of the Willys-Overland Co., whose fiscal year ends July 31st and whose 1912 production already has been shipped from the factory. Instead of dealing with convenient round figures, Willys gives the number of cars to the last one as they were shipped each month, the record being as follows: August, 1911, 284 cars; September, 869; October, 1,472; November, 1,851; December, 1,588; January, 1912, 1,826; February, 2,201; March, 2,960; April, 3,011; May, 2,605; June, 1,591; July, 539, a total of 21,788. Although there is no reason to doubt the correctness of the figures, Vice-President Bennett of the Willys-Overland Co. states that the order books of the concern are open for inspection of doubters. For 1913, the Willys-Overland output will approximate 40,000 cars.

July 22-28, Dallas, Texas—Farm and Ranch Tour under the auspices of the Dallas Automobile Club.

July 24-31, Minneapolis, Minn.—Reliability tour of the Minnesota State Automobile Association.

July 27, Rochester, N. Y.—Track races under the auspices of E. A. Moross.

July 27, Wilkesbarre, Pa.—Track races under the auspices of E. A. Cusick.

July 27, Grand Rapids, Mich.—Track races promoted by the Grand Rapids Automobile Club.

August 1-3, Memphis, Tenn.—Fourth annual reliability run of the Memphis Automobile Trade Association.

August 8-9, Chicago, Ill.—Trade vs Amateur drivers' reliability run, promoted by the Chicago Motor Club.

August 8-10, Galveston, Texas—Beach races under the auspices of the Galveston Automobile Club.

August 24, Uniontown, Pa.—Hill climb under the auspices of the Automobile Club fo Fayette County.

September 2, Washington, D. C.—Motor truck parade conducted by the Washington Post.

September 2-3, Indianapolis, Ind.—Races on the Motor Speedway, promoted by the Indianapolis Motor Speedway Co.

September 7, Hadine, Minn.—Track races promoted by the Minnesota State Fair Association.

September 17, Milwaukee, Wis.—Grand Prize road race under the auspices of the Milwaukee Automobile Dealers' Association.

September 21, Milwaukee, Wis.—Vanderbilt Cup race on the Greenfield course, under the auspices of the Milwaukee Automobile Dealers' Association.

October 7-11, Chicago, Ill.—Chicago Motor Club's reliability run.

THE STATUS OF THE CHAUFFEUR

His Relation to the Trade and Usefulness to Experts Defined by a Caustic Observer—Service Stations and Replacement Depots Examples.

"It seems to me that the position of the chauffeur in the trade never has been correctly fixed," remarked a "professor" in one of the many "automobile schools" which turn out chauffeurs almost while they wait. The "professor" is a bright chap, and when he spoke was in a more or less ironical mood.

"Of course," he continued, "we have read a lot about the influence for good or ill which the chauffeur has on the sale of trucks and on the upkeep of cars and trucks generally, and we all know that there is more or less truth in all that has been said on the subject; but that sort of thing does not fix the chauffeur's status in the industry; for, if anyone cares to tell the whole truth, the chauffeur is the 'goat' for the whole trade; that's his position. If he did not exist, it would be a sorry day for not a few dealers and salesmen, and for nearly as many so-called experts. If you do not believe it, you can obtain enlightenment almost any day by taking your car to any one of a dozen service stations or other places where experts make a good living by putting things in order and generally straightening out kinks that may have developed.

"Broadly speaking, it makes no difference whether the expert has to do with engines, or magnetos, or carburetters, or speedometers, it is always the same: no fault ever attaches to any of the various devices, even though the expert may have 'looked them over' the day before. Always the chauffeur is to blame—he has 'monkeyed' with them, or has adjusted them improperly, or failed to adjust them, or in some way or other has put them out of whack. The opinion of the experts on this point would be startling if it were not so unanimous. They've got to put the blame on someone, and the poor old chauffeur rarely fails to get it. He's the trade 'goat,' if ever there was one. He is blamed either first or last where he is not blamed all the time."

"And, say!" ejaculated the "professor," as another thought struck him, "whenever you desire to see something else that is illuminating, just drop into a few of those service stations or tire replacement depots, and you will discover the real reasons for some other things that occasionally cause wonder on the part of car owners. In many of those places, the chauffeur appears to be considered more or less of a joke, who must be tolerated, and that's about all. The treatment that often is accorded him is enough to make a man's blood boil. While no one expects him to be handled with kid gloves, or expects to find such establishments sprinkled with rose-water, the curt answers received from underlings and the long waits he is compelled to suffer constitute what I suppose some people would call a crying shame, but which, in my opinion, is a shame that properly can be expressed only by a much stronger word.

"There is one carburetter service station in New York where the chauffeurs are told that they will be given no attention, unless they bring their cars there between 8.30 and 9 in the morning. If your imagination is good, you know what that means. There are other places where they are kept waiting in line for hours, and where the slightest insistence on their part merely begets insults. Only to-day I heard one owner remark that until he himself had visited an establishment of the sort he several times had been given cause for wonder where his chauffeur killed time when sent to such places. His visit apparently removed the doubts and suspicions which had arisen in his mind.

"About the greatest satisfaction that the chauffeur obtains is when an owner drops into an establishment of the kind. The 'experts' and understudies are so accustomed to dealing with chauffeurs that they fancy that everyone who enters the place is a professional driver, and they treat him accordingly. I happened to be in a tire replacement institution not long ago when one of the understudies made a mistake of the sort. He treated the car owner—a man of means—as he was accustomed to treat chauffeurs, and, believe me, the dressing down he received will probably last him for a while. It brought joy to all the chauffeurs who happened to be within hearing.

"There is more trade 'queered' by treatment dealt out in such places than the proprietors of the establishments imagine is the case, and, take it from me, it wouldn't be a half bad idea if a manager, or someone else in authority, occasionally put on his gum shoes and otherwise disguised himself and dropped into his service station or replacement depot and kept his eyes and his ears open for at least a few minutes. He might learn why some people with whom he once did business now go elsewhere with their patronage and why the number of new trade acquisitions does not mount up rapidly."

One Way of Emphasizing Guarantees.

Some salesmen are equal to almost any emergency and do not spare the "other car" when occasion requires.

"But the Blank car is guaranteed for life," protested a prospective purchaser to a salesman of the sort.

"Yes, I know it is," retorted the quick-witted salesman, "but our car is guaranteed for a whole year."

It required several moments for the prospective purchaser to see the point.

THE BEST BUY WHAT AND WHY

Is There a Car Which Ranks Supreme as a "Money's Worth"? Problems Which Perplexed One Buyer—The Dealer's Opionion.

It was a big day in the family of the Young Attorney, for they were going to have an automobile. The head of the establishment long had talked with other members of the family over the gasolene cars which were owned by so many other attorneys and business men, while for years—it seemed years—the rising barrister had been forced to content himself with travel in electric vehicles—most of them were owned by the Interborough Rapid Transit Co. and other public service corporations.

The family had decided that with a comfortable bank balance and a practice more remunerative than it once had been, an automobile would not be an extravagance; the price, of course, they considered; for a car such as he had pictured would cost $3,500 or $4,000. Just what make had not been decided upon, and they were, in fact, further from that decision than ever. A multiplicity of catalogs had served only to confuse, so, relieved by a happy idea, the Young Attorney journeyed uptown from his office one Saturday afternoon to consult a friend in the trade who, he was sure, would put him right, even if it meant the loss of a sale.

"It's like this," he explained. "I want you to help me out as a friend and not talk to me as an agent for a car. If necessary, I'll make the threat right now that I won't buy one of your cars, anyway, so whatever you say for it doesn't count."

"What's your idea of a car—price, and so forth?"

"Well, I've been waiting a long time until I could afford to buy a car, and I want a good one; I don't want a cheap car, but I don't want to pay more than I have to. I want what some of you gentlemen have been known to term the 'best buy in the market.'"

"That situation opens great possibilities," commented the dealer, "for there is a greater variety of opinion as to the 'best buy' than on any other subject I know of."

"Yes," remarked the Young Attorney rather sarcastically, "I have gathered as much from reading about three bushels of catalogs and other literature and talking with several score of dealers. So far as I can find, everyone is right, no one is wrong and every car is the best car. But what I want from you is information as to what you call the best car to be had for the money."

"The first part of your statement may not be so far from wrong, and perhaps

Digitized by Google

most of the men you talked with are right. I wouldn't say this to anyone but you, and if you have any regard for our friendship, please don't repeat it."

"That's right," said the attorney, smiling; "I'm pleased to hear you admit your car isn't the 'best car.'"

"I admit nothing of the sort. There isn't any best car, in my estimation."

"What! No car that ranks supreme?"

"I mean, no car that is so much better than any other—considering the price it sells for."

"Well, queried the legal man, "what car, then, ought I to buy?"

"That depends on your circumstances—what your income is, what you want to pay as purchase price and what you can afford to pay for running expenses. Some years ago there were cars that had forged to the front in certain perfections until they might be considered 'best buys' compared with other cars of any price; but with things as they are to-day conditions have changed. There are some cars now that I wouldn't take as a gift and pay for their upkeep, but a man is safe with most any car. It's a whole lot like shoes, for instance. You probably pay about six dollars for your shoes, but you know well enough that you could pay half that price and get a pair of shoes that would last as long or nearly as long as those you buy now, and half the people you meet wouldn't know the difference. You buy them because you know they are good shoes and have 'class.'

"Then, take horse-drawn carriages. You can pay all prices for them, but you know that any carriage which is not ashamed of its maker's name will run and give pretty good service. Of course, it may not have the 'class,' comfort and equipment that goes with the highest priced rigs, but for a man who doesn't want to pay the big purchase price it will do very well. You could have bought a car long ago and not been extravagant. I knew you wanted one, but I let you alone, because if I influenced you into buying one I knew you would not take one of mine, because all my line is included in the so-called high-priced list. I don't propose to fix the salary at which a man can afford a car, but I do say a man doesn't have to be a millionaire to own one. The business or professional man of average means, if he can be satisfied with a lower priced automobile, can afford one. In almost every car you buy to-day you get your money's worth."

"Do you mean to say," said the attorney, who had been listening open mouthed, "that a $500 car will run as long as a $5,000 car and give the same service?"

"Not exactly that. You take the cars that sell for less than $1,000, for instance. There are parts of the car that don't get the careful finish that the costly car does, and there are details to which the attention is not paid; the upholstery may not be as deep and the reserve power may not be as great, but they run. The outside of the water-jackets may not look as pretty as that on the other car, but what needs to be reliable to ensure satisfactory work on the road is generally well taken care of. On the higher priced cars you can get any color you want, but there may be a lower-priced manufacturer who keeps his expenses down by adhering to a line of standard colors, and you have to take what is offered; but you nevertheless get a car that will permit you to take your Sunday runs into the country and you get a lot of enjoyment.

"Now, you may not want a car like that. You may have your heart set on something with more refinement and a little more power; in that case you run up the scale a few hundred dollars and you find it. The equipment may be more complete, but full equipment on all grades is fairly common to-day. Of course, the quality of equipment may vary. The finish is better as you go higher and the motors are likely to afford more power—and, too, that means more gasolene. You can grade yourself up by the hundred dollars and find a car at almost any price—and get satisfaction.

"Some men have a great desire for a 'six,' and there is no question of its desirability, the great flexibility and smoothness of running; but you won't find the 'sixes' appearing until you get up in the neighborhood of $2,000. Then you can begin to grade the 'sixes' the same as you did the 'fours.' When you look around in the factories where the cars are made which sell around $3,000 you will find them getting more paint and varnish, with rubbings which give a better finish. The lower-priced cars can't have this, because it would mean so much more on the purchase price, and the man who gets that kind of car does not expect to pay for things he does not really need—and on his Sunday outings he can drive just as well as if the car was striped with goldleaf.

"The cars which are top notchers in price are also, generally, top notchers in every detail. They have more power, they are marked by greater attention to details and by greater regard for luxury, and it is in that class that you find the 'classiest' limousines and town cars. There is every reason why these cars should afford more comfort and last longer, and though it does not always hold true, there is every reason why you should be better taken care of after you've bought the car; the price permits it.

"One of the best arguments for what I have said is on the street right here in front of this store. Take a look: There comes a car that sells for $600 or $700. Doesn't it run all right? There's one for $5,000. That runs, too, but a blind man with a few feels could tell the difference if he could rub his hands over the two. There are three or four that sell from $1,000 to $2,000, and while we have been watching there have been quite a few that sell in the low-high-priced class. You see for yourself that all of these cars run and their owners appear satisfied. Why? Because they've got their money's worth. I don't mean that every car is good, for there are some which are notorious trouble-makers.

"That man in the $600 car will be making more money in a few years, and he will also have gotten his money's worth out of his little car, so he will trade it in or sell it and get one a little better. As he keeps rising financially he will keep getting higher-priced cars, for most people grade their ability to own a car on the first cost. Now, you have denied yourself a car until you can afford the best one. There are lots of cars that will give you satisfaction as well as mine, and mine will give you as good satisfaction as any of the others. Besides, we have a few little features on our car that some of the other fellows seem to have overlooked."

"That's right, now, try to sell me a car," interrupted the Young Attorney, but without bitterness.

"Well, you're going to pay for a car just as much as one of mine costs, aren't you?"

"There may be a whole lot in what you say, and if it is true I feel like a chump for having been without a car so long. All I longed for was something that would go and would be big enough to carry my family, and, believe me, I would have been no stickler for finish; but now I want one that has real 'class.' You see, the senior member of our firm has——"

"Sure, I know," laughed the dealer, "you're in the 'class' class and you want a 'class' car—and, O say, I almost forgot, but we have a great service department here, we take care of you properly after you get the car and——"

"I guess you needn't say any more. I take back my threat about not buying one of your cars. Had I gotten this advice some time ago I might have had a lot of pleasure and bought one of your cars in the end, so I suppose I might as well buy it now. When I came up here I had no idea what you would say, but I determined to take your advice for what it was worth. I supposed you'd recommend some particular car or——"

"I did, didn't I?" said the dealer, smiling, and it really was his turn to smile.

Garage Dampness that Promotes Rust.

Though it is practically impossible in public garages to be rid of a certain amount of dampness because of the activities of the washer, conditions in private garages where no washing is done are different, and if proper precautions are taken to open windows and doors after a car that has been driven in the rain has been housed the effects will be beneficial. It scarcely is necessary to point out that dampness causes rust and tarnishes the bright work. Therefore, if the garage is kept as dry as possible, care being taken to air it out occasionally, less application of "elbow grease" to the brass will be necessary and rust will not attack the iron and steel parts.

RETAIL FIELD VIEWED THROUGH A NIGHT GLASS

The Practice of Keeping "Open House" After Dark That From an Insignificant Beginning Gradually Has Become a Habit—Its Good and Its Poor Features Laid Bare By Several Prominent Dealers—The Ultimate Influence That Is Bad.

It cannot be denied that there are certain phases in the selling of automobiles that are peculiar to that business and to it alone. While it is perfectly true that the automobile rapidly is coming to be viewed in the light of a necessity by a certain gradually increasing number of persons whose ideas of luxury as engendered by the possession of what has been expressed as "piles of filthy lucre," turn more readily to private yachts, for instance, or to aeronautics, or anything else that is more expensive, simply for the reason that it is more expensive and the glamor of the possession of one or more motor cars has partly worn away, the fact remains that in the majority of cases the automobile, and particularly the moderate-priced automobile, still represents a luxury to the average purchaser.

And as such it requires a high class of salesmanship and methods that, while resembling those that apply to the sale of other staples, are not quite akin to any of them. Necessities sell themselves, and though articles which may or may not be viewed in the same light may also sell themselves to a certain extent, their disposal as often as not entails a careful "handling" of the "prospect," perhaps in order to create the feeling that the article is, after all, a necessity, but in any case it is necessary first to obtain the good will of the intending purchaser—to make him "feel good," in other words. After that it should be plain sailing for the salesman, provided, of course, that he has the goods to sell.

Naturally, there are any number of ways in which a salesman can make the impression which must precede the actual sale: The article he is selling may do it for him; or he may, by the artful use of words, work up his prospect to the pitch of enthusiasm where he virtually sells the article to himself; and, last but not least, he may place himself in the background, efface himself, so to speak, place his whole time and pleasure and efforts at the disposal of the intending purchaser. Of course, the last measure often entails hardship and requires that a salesman devote time to the sale of his products which otherwise would be spent in the pursuit of pleasure or in the bosom of his family.

And the retail automobile business is peculiar in this respect: It often is necessary, by reason of the business interests of the intending purchaser, that appointments or demonstrations be arranged to take place after the close of what generally are considered to be business hours. Of course, the intending purchaser of an automobile knows, as well as the intending purchaser of any staple knows, that the salesman who is keen to dispose of his wares will not object to a little overtime work, and consequently he is not averse to making evening appointments even where it is possible for him to transact the business during the day. The salesman, on his part, is willing that this should be so. It is one way of creating an impression, of obliging the "prospect" and of giving him a sense of his own importance in the transaction.

And though it undoubtedly has been the desire on the part of agents to increase the amount of business done that has prompted the practice of keeping "open house" almost until the "wee sma' hours" of the morning, it has been the feeling back of it all to oblige the customer that has been responsible for the movement. But whether the practice of keeping salesrooms open in the evening really is good for the business, or, in other words, if it really pays, if viewed from every angle, is largely a matter of opinion. Of course, conditions vary according to the size and the location of the city which harbors the salesroom. In a small city, for instance, where the salesroom is located on the main thoroughfare along which crowds of persons on pleasure or business bent wend their way at night, keeping the salesroom open at night might pay handsomely; on the other hand, it might not do so, much depending on the temperament of the natives.

On Broadway, in New York City, where are located most of the principal automobile salesrooms, however, it is the concensus of opinion among those who do not close their doors promptly at half-past five or six in the evening, that keeping open pays, though, strangely enough, it is pointed out by more than one manager that the practice is bad for the business in the end. All express a desire to get out of the habit, though it is admitted that it is practically impossible to do so, without considerably decreasing the amount of business done, for the simple reason that it has become a habit and the automobile purchasing public has become accustomed to it.

C. T. Silver, of the C. T. Silver Motor Co., which distributes Overland cars in the Metropolitan district and environs, modestly claims the credit, or the discredit, of having inaugurated the practice, and is one of those who has no hesitancy in wishing it might be stopped. His salesroom on Broadway is open every evening until midnight.

"If it did not pay to keep open in the evenings we would not do it," Silver sums it up, "and neither would anyone else. We have five salesmen here, and it is the duty of each to take his turn at night duty. As he does not have to report the next day until one o'clock, it is not very hard on him, and anyway no salesman works very hard when he does work. If we sold three cars in a year by keeping open in the evenings we would consider that it paid, for it costs nothing to keep open. As it is, we sell more than three cars, and, besides, it is good advertising. Persons drop in here after the theater to look over the line, or to get a catalog, or to ask any of the innumerable and foolish questions that enter their minds, and in a great many cases we get real live "leads" which later can be closed up. Yes, it pays, all right, but it is bad business, for it lowers somewhat the dignity of the salesman in that it gives an appearance of servility which, as a rule, they do not like. The salesmen themselves want to abandon it, but that is nothing out of the ordinary, for every salesman seems obsessed with the idea that his own pleasure ought to take preference over his business interests and, as I already have said, none of them ever work as hard as they might, despite the fact that it manifestly is to their own good to do so. Personally, I wish we could quit keeping open, but we can't; and there you are."

W. B. Raymond, who is sales manager for the Abbott Motor Co. of New York, which handles Abbott-Detroit and Regal cars, has even more pronounced views on the subject and goes so far as to say positively that in his experience it is a very bad thing for the business.

"When you consider," he says, "that the average automobile salesman is nothing more than a slave who works 365 days in the year—vacations are practically impossible for the reason that if you leave your 'prospects' you get out of touch with them almost immediately and someone else snatches them—it is pretty hard on him to expect him to do night duty as well as day duty. Double work naturally impairs his efficiency as a salesman, and there is no doubt in my mind but that in the end we lose out. Here, in the evening, we get some mighty good leads, and in a number of cases perfect strangers have strolled in, and before they got out we had a signed contract in our possession. The persons

Digitized by Google

who drop in here in the evenings are much the same as those who come in during the day, the only difference being that in the evening we are less likely to be interrupted by the telephone or by 'kicks,' and we have a better chance to get close to 'prospects.' We did not start the practice with the idea of catching 'floaters.' It was started entirely by accident. Some of the boys got into the habit of dropping in here in the evening to smoke and 'chew the rag,' and as soon as it became known that some one was here theatergoers and others commenced to drop in, and before we knew it the habit had grown. Now we have to keep a man here every night, though it is good in one way. As each salesman is required to make out a certain number of reports and has a certain amount of office work to do every week, we have arranged it so that he can do it on the night he is on duty. In this way he can kill two birds with one stone. But on the whole, this keeping open in the evenings is bad business, and I am going to stop it next week. But I am going to commence it again just as soon as the new models arrive."

As expressed by one of the salesmen at the Buick agency, the practice is good—for the salesmen. "For," he explained, "as we work on a commission basis, we don't mind staying here one night a week, and whatever we get out of it is virtually 'velvet.' At present it is pretty slow in the evenings, but we have sold all our allotment and we don't mind it very much, for any persons who come in are immediately made 'prospects' for the new models. As soon as we get the new cars there will be a lot of 'velvet' distributed, too, if we can judge by the number of cars we have sold 'after hours' in the past." At the Oakland agency much the same view of the situation is taken, one of the floor salesmen explaining that "though a lot of live 'prospects' come in during the evening and night business had been pretty brisk of late, it was 'terrible' hard on the salesmen, who one night each week are required to be on duty from eight in the morning until midnight."

Over in Brooklyn, which by reason of its proximity to Long Island points and the position of its automobile row virtually in the path of all the cars en route to Coney Island and other resorts, rapidly is assuming to considerable prominence as an automobile distributing center, conditions are practically the same as they are in New York City proper, the only exception being that, if anything, the practice of keeping salesrooms open in the evening is more general than it is across the East River. After nightfall, Bedford avenue becomes a veritable blaze of glory, and there are few with designs on the ownership of a car who can resist the appeal of the brightly illuminated salesrooms. And invariably those who hesitate are lost, that being the phraseology adopted by Louis Burstein in discussing the matter with the Motor World man. Burstein is the treasurer of the Tanner Motor Car Co., which has the distributing agency for Everitt and Oldsmobile cars on Long Island. His salesroom is kept open every night "till the last customer has left," no set closing time being the order.

"Of course it pays," said Burstein, reiterating what C. T. Silver had said, "or we would not keep open. I believe that the salesroom where moderate-priced cars are sold should by all means be kept open in the evenings, for the purchaser of a moderate-priced car generally has a moderately strenuous time filling his pocketbook in daylight hours and cannot afford to take time enough from his business to examine a car and make up his mind to purchase it. We have had several men drop in here through the day for a catalog, and have made appointments with them for an evening demonstration and sold them cars at night. If we had refused to do business at night we would have been out of pocket. That's all there is to it. Time and again I have had men with their wives drop in here in the evening, presumably after the theater, just to look over the line, and before you know it I would have them signed up. If the agency had not been open we might have gotten the business in the day time, but then again someone else who does keep open at night might have gotten it, for the reason that the man of the house could not get around during his business hours. And that explains the situation in a nutshell: If one agency keeps its doors open in the evenings then they have all got to do it, or the one who remains open will get the business. I wish I did not have to keep open at night, but it has become a habit—everyone in Brooklyn knows that the Tanner Motor Car Co. keeps open house in the evenings—and we just can't shake it off. Still, on second thought, I don't know whether I would want to do so, after all; for we are doing a good business here nights that we might lose otherwise." "Another thing," he added, "it is good advertising for us to be open at night, but the minute we close the doors, whether it is eight o'clock or midnight, the lights go out, for it does not do a bit of good to pay electric light bills just to let people look through the windows at the cars. The day has passed when you sell a car that way—on looks—and the sale of a car to-day requires that a man be right on the job to 'sell' the car, and, if necessary, to hold the pen that signs the contract."

Whether the practice of keeping automobile salesrooms open during part of the night actually pays in the long run or not, there is no such uncertainty regarding the remuneration of the night-blooming variety of supply store, in the mind of J. H. Parsons, who for the past six years has been located in the heart of the automobile district on Broadway in New York City. Despite the fact that his sign reads "Talk with Parsons, day and night," which might lead to the supposition that the store was kept open all night, it is closed at about 10 o'clock, which is, as Parsons put it, "plenty long enough."

"Frankly, it does not pay me to keep open," he said. "I may take in anywhere from one to five dollars a night—last night I took in $2.30—but that is not a drop in the bucket. Why, then, do I keep open? Well, the truth of the matter is I have nowhere else to go, and if I stay here I catch whatever business there is floating around, and it keeps me out of mischief. "But it does not pay," he added, with faint pathos, "and any man who thinks it can be made to pay is a fool, for I have been at it a long time and I know whereof I speak."

Hot Water for Removal of Carbon.

Carbon removal is one of those necessary things which must be attended to every now and then if the best of results are expected. The motor need not be taken down, however, save in cases of very heavy deposit, which cannot be removed without scraping. For most deposits the use of a carbon removing chain or solution, several of which are on the market, will help considerably. The injection of "simple hot water," according to a gas engine machinist of no mean experience, is, however, the best method of removing carbon yet devised. The motor is warmed up, and then run light at high speed. The warm water is poured into the auxiliary air inlet of the carburetter until the motor begins to "choke." Several applications, he declares, will suffice to flake off the carbon, even in aggravated cases. It goes without saying that, immediately after the hot water treatment, oil should be applied to prevent the formation of rust.

Celluloid to Illustrate Body Colors.

Making use of a scheme that at one time was in more or less general use by such plebian persons as tailors, at least one automobile sales agency has adopted a novel though not new method of illustrating to prospective purchasers the effect of different finishes on its various models. The necessary apparatus consists of several sheets of clear celluloid upon which is printed in black the outline of the various models. By placing the celluloid over the color specimens, it is possible to judge at a glance and generally with entire satisfaction the ultimate effect that would be obtained if the car were finished in that color. In some cases the scheme is rendered more effective by gilding the celluloid to represent the parts which ordinarily are polished brass.

Filler Caps Broken by License Tags.

It is bad practice to fasten a license tag to the radiator filler, unless the lower portion of the tag is braced against the radiator frame. A very slight knock on the lower end of the tag is liable to tear the base of the filler from its fastening on the top of the radiator, owing to the leverage through which the force acts.

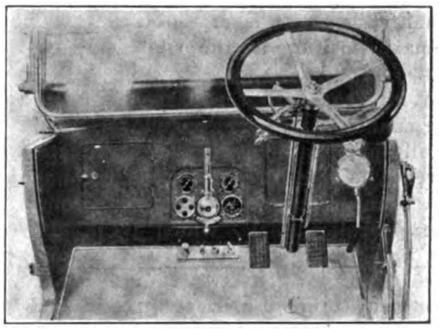
PIERCE MAKES TWO DEPARTURES

Adopts Tubular Drive Shaft and Force-Feed Lubrication—Also Employs Air Starter and Westinghouse Lighter.

Always distinctive by reason of beauty of outline and finish that has served as an infallible indication of their A1 material and superb workmanship, Pierce-Arrow cars of the newer series—the series that embodies the refinements and the slight alterations that experience with previous models has suggested—have been made more than ever the exemplification of all that is right and proper in automobile construction.

As heretofore, there are three motor sizes in the line, though the designation of the corresponding cars has been altered to permit of the elimination of all reference to the year of their make, letters being substituted, merely for factory listing purposes, it is explained, and to them are prefixed numerals which indicate the horsepower of the various models. Thus, for instance, there are the 66A, the 48B, the 38C and the 48D, the last named being a new model as regards the body and equipment, though the chassis differs little from the standard 48-horsepower car. All are equipped with six-cylinder motors, as they have been since 1908, when their manufacturers, the Pierce-Arrow Motor Car Co., of Buffalo, N. Y., put all its eggs in one basket, so to speak, and discontinued the manufacture of "fours."

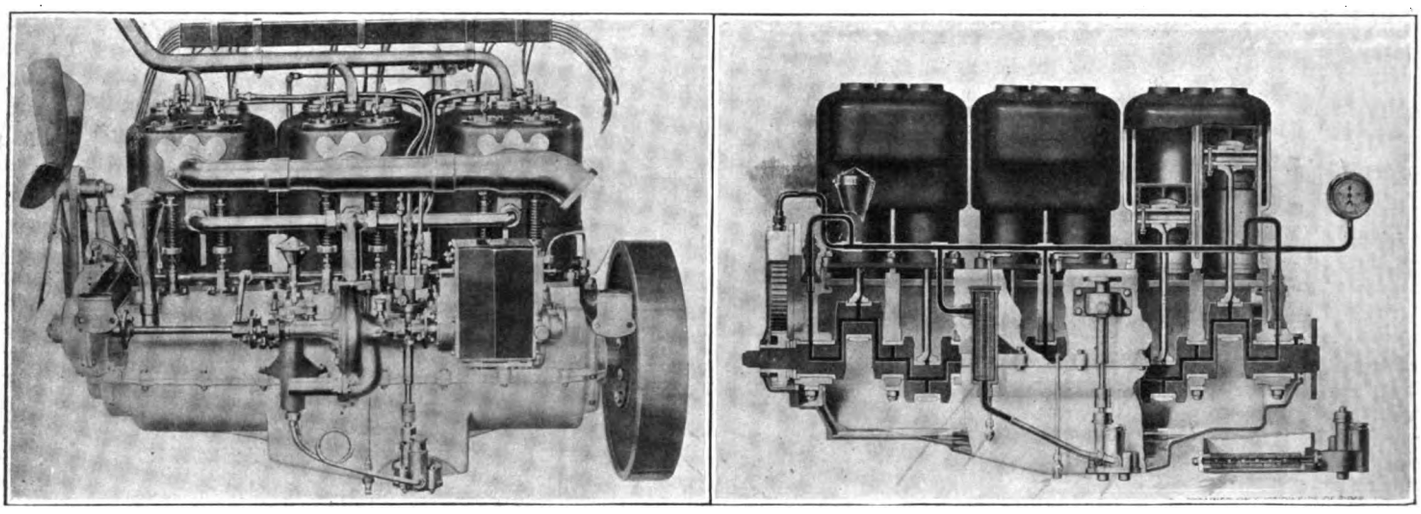


PIERCE-ARROW MODEL 38C—A FIVE-PASSENGER TOURING CAR

Though radical changes in design are not looked for in the products of the Pierce-Arrow company, several alterations nevertheless have been made, which in view of the consistent continuance of well-tried features for a number of years almost might be termed radical without danger of straining the meaning of the word, at least as applied to Pierce-Arrow cars. Thus, for instance, the gravity feed lubrication system which has been one of their distinguishing marks, and which over a long term of years has given service the satisfaction of which has been indicated by its continued use, has been replaced by a force-feed system, in which the oil is forced under pressure to every main and auxiliary bearing. The other alteration of an epochal nature which has been made, and it is noteworthy that there have been only two, is the substitution of a tubular propeller shaft for the solid shaft that has been used in the past.

Such other alterations as have been made are largely in the nature of additions to the equipment and do not affect the general design or construction. Perhaps the two most important changes in equipment are embraced in the addition of a complete dynamo electric lighting system to all the models and the addition of a compressed air engine starting system to all except the model 48D which is fitted with an acetylene priming device. In other respects, the equipment is unusually complete, as becomes the products of a manufacturer that always have been marked by extreme liberality, and includes windshield with patent ventilators, Pierce-Arrow demountable rims with two extra rims, electric head, side, tail and dash lamps, Warner speedometer and clock, gasolene tank gauge, gasolene primer, power tire pump, Klaxon and bulb horns, shock absorbers, trunk rack, foot rests, coat rails, tools, spare parts, and so forth. Despite the amplification of the equipment, however, the prices of the various models remain unchanged, with the exception that the 38-horsepower model now lists at $4,300 instead of $4,000. The 66A, in seven-passenger touring form, lists at $6,000, and both the 48-horsepower models list at $5,000. The prices for models 48B and 66A in limousine and landaulet form are the same—namely, $6,100 for the former body and $7,100 for the latter, the same prices applying to the suburban and landau types; the vestibule suburban and landau list at $6,300 in model 48B and $7,300 in model 66A.

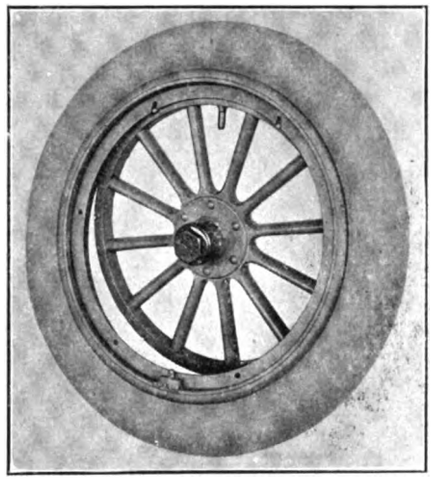
Except for the fact that the stroke of the 38-horsepower motor has been increased from 5⅛ inches to 5½ inches, the bore being 4 inches, motor sizes remain the same, the cylinders of the 48- and 66-horsepower models measuring 4½ x 5½ and 5 x 7, bore and stroke, respectively. Treating all the motors as mechanical duplicates with respect to their design, the most noteworthy alteration which has been made concerns the oiling system, which, as has been pointed out, is brand new. Under the new regime, the oil is circulated through a hollow crankshaft by means of a gear-driven pump, the lubricant being delivered to a manifold in the crank chamber, whence it is led by means of suitable ducts to the main bearings and to the timing gear train. By means of pipes along the connecting rods, the oil is led to the wrist pins, thus providing them with a separate and positive feed. The engine starter, as may be seen by the picture, is of the orthodox type, in which the component parts are a four-cylinder compressor driven from the forward end of the change gear mechanism, a reservoir, a distributer, which is driven from the camshaft, and a conveniently located pedal valve. Incidentally, provision is made for inflating tires from the reservoir.



In working out the method of ignition, no inclination to place entire dependence on any single system has been shown. Instead, a Bosch high tension magneto system with variable advance is supplemented by a master vibrator and coil system operated by means of a storage battery. The magneto is located on the left side of the engine, and the shaft which drives it serves also to drive the lighting dynamo. The dynamo itself is of Westinghouse manufacture and forms the principal unit in the recently perfected Westinghouse system with which all the cars are equipped. Current supplied by the dynamo during the time the engine is running is stored in an accumulator of liberal capacity, the system being completed by the addition of the usual switches and automatic cut-out, the purpose of the latter being to prevent the storage battery discharging itself through the dynamo when the engine is idle.

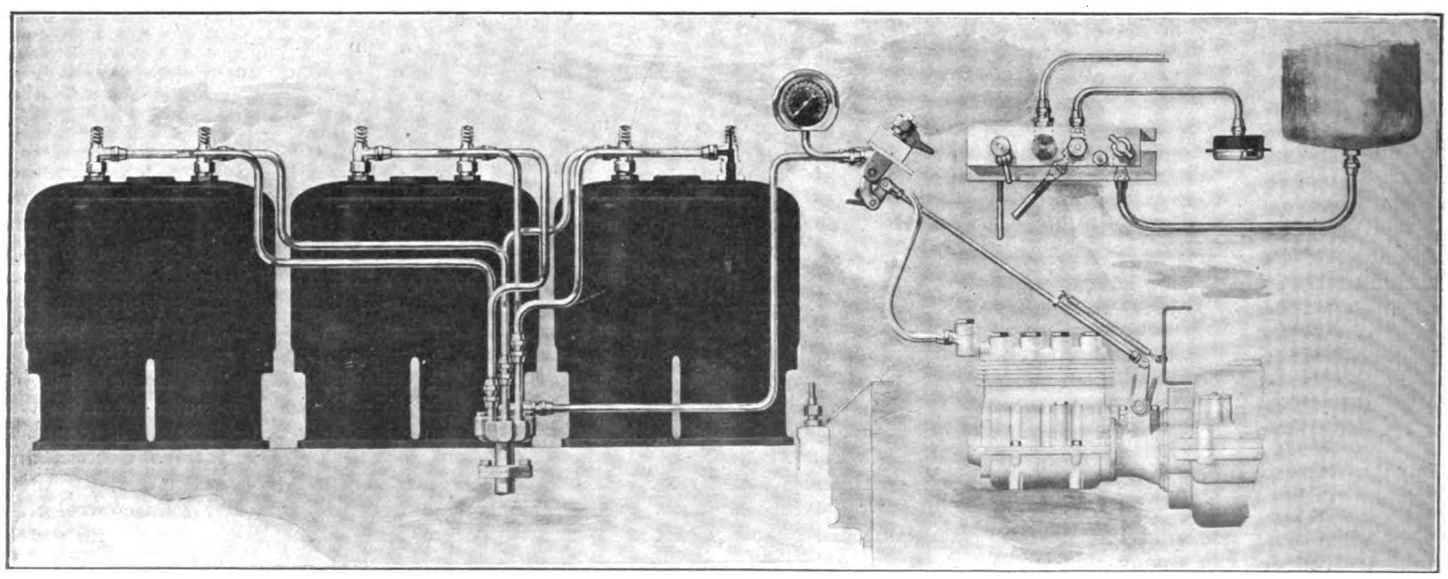
CENTRALIZED CONTROL SYSTEM

In connection with the arrangement of the dash apparatus, particular attention has been given the centralization of control, and to this end the various electric, air pressure and oil pressure gauges, together with the necessary valves and control elements have been placed on a central panel almost directly under the driver's eye. In order to facilitate operation of the car at



Digitized by Google

TWO VIEWS OF THE PIERCE-ARROW MOTOR, SHOWING DYNAMO POSITION AND NEW OILING SYSTEM



night, the panel is illuminated by means of an electric light carefully located and shaded to obviate the possibility of the glare detracting the driver's attention or otherwise disturbing him. The remainder of the control elements—that is to say, the steering wheel and the gear shaft and emergency brake levers—occupy their customary position at the right side of the car.

With regard to the chassis proper and the running gear—the four models are practically identical except for a legitimate difference in size of parts—the most important change which has been made concerns the propeller shaft, which is tubular in section. In explanation of the reason for the change, which is a radical departure from any other American practice and is exclusive with the Pierce-Arrow cars, it is pointed out that the new construction permits at once more rigid and less weighty construction, the ultimate effect being to increase the already high factor of safety which always has been allowed throughout the cars. The change, of course, has necessitated other changes to conform to the new construction, and these include the adoption of new universal joints of somewhat greater bearing surface and a slight rearrangement of the rear axle housing to make room for larger and more substantial driving and differential gears. Another important advantage which the tubular propeller shaft has is that its bore forms a convenient method of insuring the constant and efficient lubrication of the rear construction.

PIERCE-ARROW DEMOUNTABLE RIM

As in the past, the clutch is of the aluminum leather-faced, cork insert, cone variety of liberal contact surface. Though it is light in construction, the effect of the male member spinning when withdrawn and causing difficulty in engaging gears is eliminated by the addition of two brakes, one on either side. Power is transmitted to the semi-floating axles through the intermediary of a four-speed, selectively-operated change gear mechanism in which the high gear is direct drive. The springs, as heretofore, are of the semi-elliptical variety in front and three-quarter elliptic in rear; their efficient action is ensured by the addition of shock absorbers both front

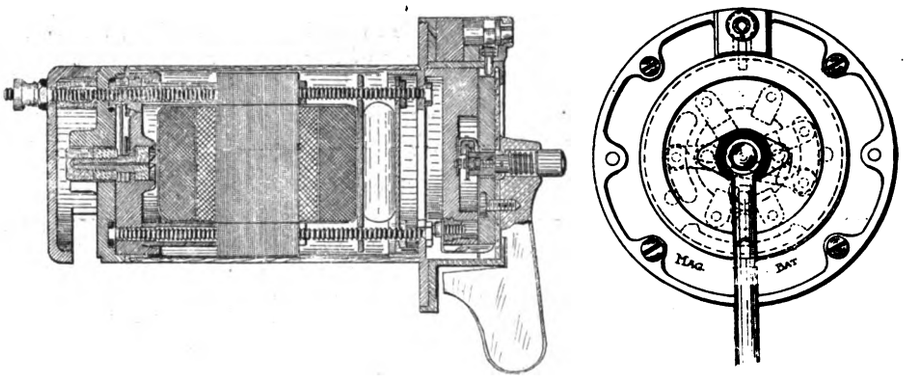
DETAILS OF THE COMPRESSED AIR STARTING SYSTEM WITH WHICH PIERCE-ARROWS ARE EQUIPPED

Digitized by Google

and rear. The brakes are internal expanding, operated by pedal, and external contracting, operated by side hand lever; both sets are equalized.

The wheelbase of the roadster, four- and five-passenger cars in all three models remains the same—namely, 119 inches, 128 inches and 133½ inches, respectively. On the seven-passenger and enclosed cars, however, it has been increased from 127, 134 and 140 inches to 132, 142 and 147 inches, respectively. Tire sizes remain the same, though the equipment has been considerably improved by the addition of demountable rims of a new type, which are manufactured by the Pierce-Arrow company itself. As may be seen by reference to the accompanying picture, the construction of the rims is quite different from anything else of the kind and has been developed as the result of a demand for a device of this kind in which complication has been reduced to the point where the application of the rims requires the minimum effort and experience; giving indication of the careful manner in which the development has been carried on, it is pointed out that experimentation has been carried on for no less than three years before the present construction finally was adopted. The rim is held in place by six bolts, two of the holes for the holding bolts being slotted; the purpose of the slots is to permit the operator to slip the rim in place where it holds itself instead of requiring that it be held until some of the bolts are replaced. Otherwise, the rim is constructed on the quick-detachable principle which permits of the removal or replacement of tires in the shortest time.

In the bodies little room for improvement has been found, the sides being of the proper height with regard to the dash and engine hood to give the very much desired straight-line effect, and as many as possible of the external protuberances having been relegated to less conspicuous places. Storage space is unusually liberal and, in the case of the forward compartment, has been carefully worked out by providing miniature part lockers built directly into the cowl dash. Limousine bodies, as heretofore, will be distinctive by reason of the arched effect over the doors, which construction is calculated to increase head room and also to add to the attractiveness of the body.



Compound That Preserves Steel's Polish.

Unless parts made of polished steel are rubbed frequently or kept covered with grease, rust will form. A method of treating the surface so that it will preserve its polished appearance for months without attention, however, is to smear on the surface a paste formed of one ounce of camphor dissolved in a pound of melted lard to which a quantity of black lead has been added. Allow the preparation to remain on the surface overnight and then wipe clean. The treatment will also keep nickel bright without constant polishing.

WAX ELIMINATED BY SPLITDORF

Brings Out Transformer of Purely Mechanical Assembly—Hot Spark Insures Almost Infallible Engine Starting.

Supplementing a line of magnetos, spark coils, spark plugs and switches, the completeness of which is one of its excellent features, the Splitdorf Electrical Co. of New York City has developed and practically has ready for the market a new type of transformer which is a radical departure from anything of the kind that has come from the Splitdorf works. It is styled a tube-switch-transformer, and as its name suggests is of the variety in which the low-tension current transformer is enclosed in a dash-mounted tube which serves also to carry the usual switch for making and breaking the ignition circuit.

SECTIONAL VIEW OF NEW SPLITDORF TUBE-SWITCH TRANSFORMER

Though the idea involved in the arrangement of the component parts is not brand new, but is rather an adaption of designs of a similar kind which over a number of years in hard service have demonstrated their ability to withstand the wear and abuse to which such things generally are subjected, the construction of the device is new and embodies a number of features calculated to increase its efficiency and to reduce wear and tear to the minimum. Thus, for instance, the principal feature of the apparatus, barring its newness to the Splitdorf line, of course, is that the parts are assembled mechanically, there being no rosin, wax or other compounds used to maintain the component parts in their relative positions. The immediate effect of this construction is to eliminate the possibility of heat from the engine causing derangements of the wiring. Incidentally, troubles caused by such compounds cracking, due to road or engine vibration, are entirely avoided.

Despite the fact that the new apparatus is small in size, the overall measurements being but 2¼ x 4¼ inches, contact bearing surfaces are unusually liberal and great pains have been taken to ensuer positive contacts under even the most adverse conditions. To this end, the rubbing contact surface is firmly imbedded in suitable insulating material and the contact blades are of simple bent form. Inasmuch as the rubbing surfaces are brightly burnished, wear in the parts is practically insignificant. By way of eliminating the possibility of verdigris forming and causing poor contact, particular care has been taken to make the switch parts perfectly waterproof. These parts, by the way, are heavily constructed to prevent damage resulting from short circuits and also to resist hard usage.

The arrangement of the whole apparatus is such that it forms a dual system in combination with an engine starting device which ensures positive starting, regardless of whether the circuit breaker of the magneto is open or closed. By reason of the winding, pressure on a button mounted in the dash plate causes an extremely hot spark to take place in the cylinder, which is ready to be fired. To start a cold engine merely requires that it be cranked once or twice, in order to fill the cylinders with explosive mixture, when, with the switch thrown to the battery position, pressure on the push-button serves to ignite the mixture and start the motor. Another of the refinements which has been incorporated in the design is the addition of a lock by means of which the switch may be locked in the "off" position to prevent the theft of the car. Differing from other and similar constructions, however, the key may be withdrawn from the lock while the switch is in operation, and need not be left in place during the time the engine is running.

Where Automobiles Have Lost Ground.

Yucatan, Mex., is one of the spots on the globe in which the automobile really has lost ground. According to the report of the American consul, in Merida, the capital of Yucatan, the streets of which are well paved, the number of automobiles licensed has declined from 200 to 109, six of which are electrics. He attributes the loss to the decline in the price of sisal, the chief product of the district. There are four garages in Merida, where a chauffeur's license costs 75 cents a month and a car license $5 per month.

CRITICIZES OUR EXPORT METHODS

Well-Intentioned Purchaser Points out Conditions He Encountered—Red Tape and Price-Juggling Involved.

Because of the general reaching out for foreign trade and the more or less general establishment of export departments in the larger automobile factories, it naturally has been assumed that the handling of inquiries and orders from abroad has reached close to a fine art. But apparently not all of the lessons have been learned as they should be learned, and inattention to even simple requests for catalogs is more common than should be the case, while delays caused by red-tape methods and other circumlocution, to say nothing of juggling of prices by foreign agents for American cars, are such as give cause for wonder. Instances of the sort have been heard of before, but the best opportunity American automobile "export departments" have had to see themselves as others see them is contained in a communication addressed to an American consul in Russia by an exasperated would-be purchaser whose strictures have been made public for the good that they may do.

"For the past six months I have sought information of and written to various automobile companies which advertise in the well-known weekly and monthly American periodicals," writes this well-intentioned critic. "One of these companies replied that it had no cars for export and that my inquiries would be answered and a catalog sent by an exporting connection in New York. I have yet, after some months, to receive these. Two other firms, though I have written them twice, have never sent me their catalogs. I finally wrote their English agencies, and in this way secured the information I wanted.

"Another firm, very prominent in the Glidden tour last year, when quoting the price of a certain type car, told me I could have it shipped direct from New York, gave the cost of packing, etc., f. o. b. New York, and stated that my letter had been sent to its London agent, who would reply to my inquiries regarding certain mechanical features. Eventually the London representative wrote me they had referred my letter to their agent in Russia, who finally partly replied to my letter, but in French. I then discovered that I was supposed to pay, not the American advertised price plus cost of getting it here, as I inferred from the manufacturer's letter would be the case, but approximately $150 more for the two-cylinder runabout this firm sells for $625 than I could have bought the same car for from an agent in the United States, had it packed, paid ocean freight and duty and landing charges, and thus got it here myself.

"The other vehicles about which I sought information have been touring cars, ranging from $690 to $1,600, and in one instance a 15-hundredweight capacity delivery wagon, intending to try one of the latter and, if satisfactory, to purchase two more for the company's use. In but three cases did I receive the courtesy of a direct reply to my inquiries. One or two concerns informed me that my letter had been referred to their London or Paris agency; but generally I did not receive their American catalogs which I wanted, and the first acknowledgment of my letter would be from European agents with pamphlets containing the brief specifications given in the American advertisements, with the added statement that any further information required would be furnished by some 'Mr. Ivan Ivanovich' or other, in Odessa, Moscow, or Petersburg, and from whom, in some instances, I have received letters replying in French or Russian to my inquiries put in English and sent to America. From others I have yet to hear.

"Briefly, I find that, with the exception of one firm from which I have not yet had time to get its London prices, I cannot buy a car of any of these makes by writing to America; that in 70 per cent. of the cases I cannot get the courtesy of a direct reply to my letters written in English; and that I am supposed to pay, without any exception other than the one just referred to, $75 to $417 more than the same cars are sold for by agents in New York, allowing all costs of crating, freight, duty, etc.

"Most striking is the case of one firm which sells a touring car for $690 at its agencies in the United States and for $1,337 in St. Petersburg. It costs $25 to crate this car, approximately $75 for ocean freight either to St. Petersburg or Batum, and $110 for duty, with, say, $10 landing charges and $10 for insurance, bringing the total to approximately $920. I wrote this firm in America for full information, asking them to send me descriptive literature. I eventually got two catalogs and a letter which I consigned to the waste paper basket on seeing I was supposed, if I purchased this car, to pay $417 in excess of its cost in America. The cars priced $1,000 to $1,500 will, in the same manner, cost anywhere from $75 to $200 more than I could get them for by paying all expenses myself, if I were permitted to purchase direct in the United States.

"Far different has been my experience with British manufacturers or London agents of French, Belgian, German and Italian cars. In 12 different inquiries on cars costing $1,750 to $4,000 I have in all cases received the fullest information.

"As a contrast to the apparent arrangements made by American manufacturers for the sale of their product abroad it is interesting to note that the makers of one of the best English cars offered a friend in Batum the agency of their cars for the Caucasus. It was my privilege to read their letter, and the friend was offered a per cent. reduction on the advertised and catalog price of their cars as his commission on each car sold; but this per cent. reduction was not to apply to any car sold in the district to a customer who bought his car direct in England independently of the agent. In other words, if I wanted this car I could buy it either direct from England or from the Batum agent. In either case, whether I bought it here from the agent or whether I purchased it in England and paid the charges of getting the car out myself, the price of the car would be the same to me.

"Although knowing I wanted the car purely for private use and that I was in no way interested in the sale of automobiles, four European firms offered me the car I inquired about at a reduction of 12½ to 17 per cent. simply to have one of their cars represented and running in this section.

"American cars, particularly in Russia, should have a splendid field. The British cars are built for the superb English highways and are too low, too heavy, and have too little road clearance—seldom 8 inches—for the Russian roads. There are a few firms that make what they call a "colonial" model with 9½ to 13 inch road clearance, but these cost about $2,750 in England, and with the superb coach work on their bodies are more expensive and luxurious than the masses in Russia can afford, or would appreciate to the extent of being willing to pay the difference in cost between an English and an American body. The French and German cars have more road clearance than the usual British car, but are also too expensive to enjoy widespread use and popularity here in Russia.

"The American car, however, that sells for $1,000 to $1,250 for a four-seater is, in road clearance, in weight, in price, and in finish, just what is required here to enjoy wide popularity and meet the pocketbooks of thousands who cannot afford a British, French, German, or Italian car—if they can be sold in Russia for what American agents sell them plus cost of freight, crating, and duty."

Fire Truck's "Stalling" Excites Lafayette.

It will go hard with the man who "monkied" with the carburetter on the motor fire truck which recently was acquired by the Lafayette (Ind.) fire department, if the detectives investigating the cause of stalling of the apparatus while on the way to a fire should perchance happen to lay hands upon him. The motor "choked" soon after the company left the fire house, and was only started after an expert from Detroit had discovered that some one had "cut down" on the needle valve. That it was done purposely is the accepted theory of the mayor and of the Board of Works, in view of the fact that considerable feeling had been aroused when the "self-propeller" was installed and the fire horses, which were no longer needed, were abandoned and the services of several firemen dispensed with.

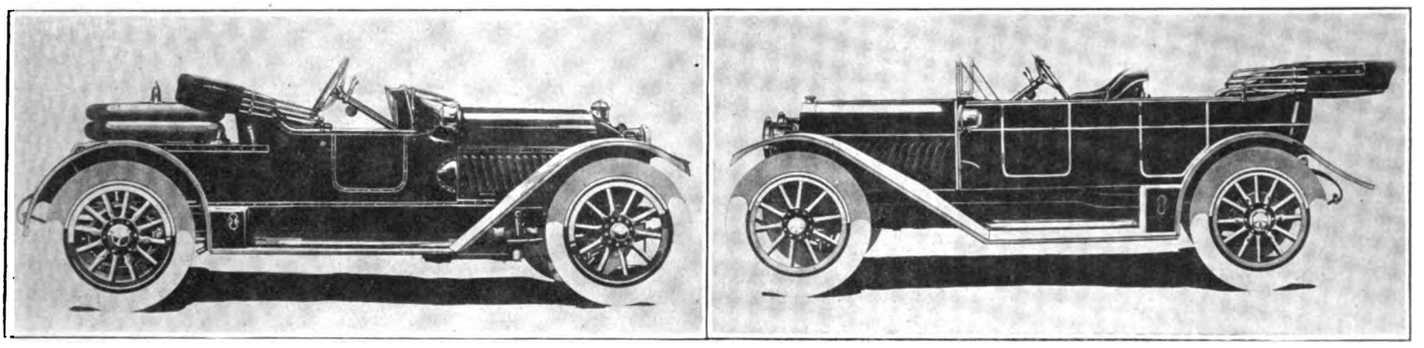
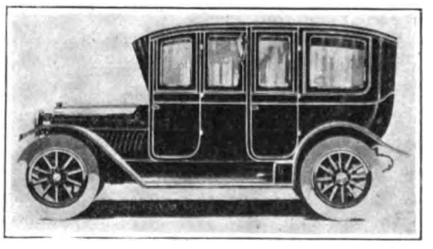
ABBOTT ADOPTS UNDERHUNG SPRING

Increased Power and Engine Starter and Lighting System in Separate Units Mark New Models—Other Refinements.



In common with several other manufacturers who have adopted the plainly understandable method of designating their products by model numbers which also serve to indicate the power of the engine, the two chassis which will go to make up the offering of the Abbott Motor Co., of Detroit, Mich, hereafter will be styled the 44-50 and the 34-40, both, as heretofore, being fitted with four-cylinder motors. As the old designations were 30 and 44, respectively, it may be gathered that both cars have been materially increased in power. As a matter of fact, though the salient features upon which the Abbott-Detroit reputation has been built have been retained both cars have been increased in nearly everything else as well as power. The increase is so marked in both of the cars that they are virtually new models throughout, particularly the 44-50, which by reason of much refinement and the addition of an electric lighting and engine starting system—this feature is common to both models—has appreciated materially in value if measured either by the mere dollars and cents of its price or by a critical analysis of its structural details.

Despite the fact that there are but two chassis cataloged by the manufacturer, the variety of body styles that are included in the line gives plenty of latitude for choice, and each individual car leaves little to be desired in the completeness of its equipment. Thus, for instance, there will be seven distinct body styles. Five of them, including the "battleship" roadster, which made its debut early this year and which since has given evidence of assuming to the leadership of the line; a small tonneau touring car, a five- and a seven-passenger touring car and a luxurious-appearing Berline limousine, are mounted on the 44-50 chassis. The other two, which are a three-passenger roadster and a five-passenger touring car, are mounted on the 34-40 chassis.



In the matter of equipment, the new electric lighting and engine starting system occupies the premier position, of course. It differs from other systems of the kind chiefly in that the motor starter and the lighting dynamo are separate units and are completely divorced from the ignition system, which is of the Splitdorf dual type and is a complete unit by itself. The electric starting motor is very compact and is bolted to the side of the crankcase. It drives the motor through a train of gears and a positive friction clutch, which effectually precludes the possibility of damage resulting to the starter in the case of a back-fire. Power is derived from a storage battery of liberal capacity, and this is maintained in a constantly charged condition by means of the dynamo, which is separately mounted and driven. As an additional precaution against back-fires, the starting operation is controlled by means of the spark advance lever, which must be in the fully retarded position before the engine can be started. The remainder of the system includes the usual automatic switch to prevent the discharge of the battery through the dynamo when the engine is idle and a complete complement of head, side, tail and speedometer lamps. The remainder of the equipment, excepting the top and side curtains, which are listed as an extra, includes Booth demountable rims, tire irons, tool kit, jack, pump and tire repair outfit.

"34-40" STANDARD ROADSTER

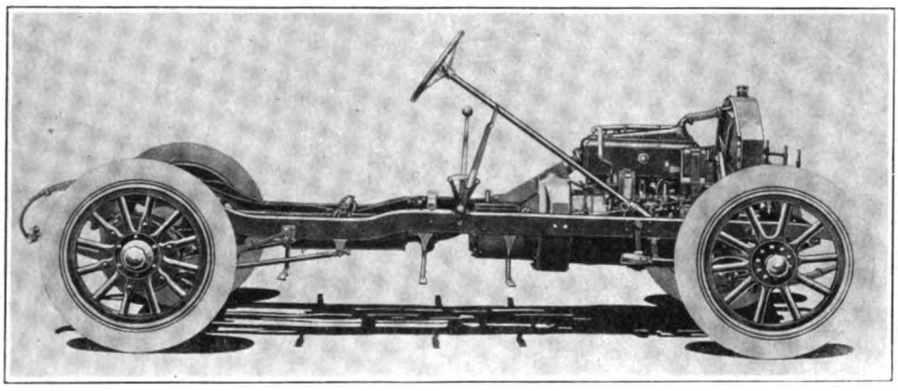
TWO ABBOTT-DETROIT MODELS ON THE "44-50" CHASSIS—"BATTLESHIP" ROADSTER AND TOURING CAR

"44-50" ENCLOSED LIMOUSINE

Other than the more or less minor detail improvements which have been made in the larger model and which must be reckoned with by reason of their undoubted influence on the efficiency of the car as a whole, the most noteworthy change which has been made in the chassis concerns the spring suspension. By way of increasing the resiliency of the springs, and thereby raising the easy riding quality of the car to an even higher standard, both sets of springs, front and rear, have been hung beneath the axles instead of over them, as heretofore. Another of the advantages which this system of suspension possesses is that the center of gravity of the car is appreciably lowered and its stability correspondingly increased. The front springs are of the semi-elliptic variety and the rear members are of the three-quarter elliptic type, both sets being long and of proportions calculated to render the use of shock absorbers unnecessary.

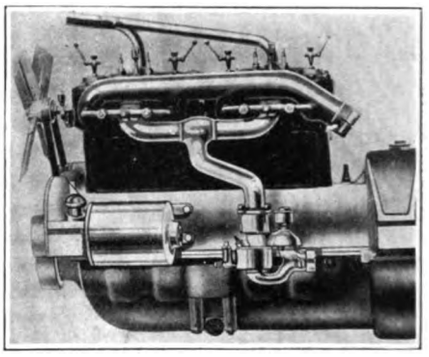
Except for the addition of the lighting and starting system, which has necessitated very slight rearrangement of some of the minor details of the motor—it is of the well-known Continental make—it remains practically the same, the cylinders being of the L-head type cast in pairs and measuring 4½ x 5½, bore and stroke, respectively. Cooling is effected by pump-circulated water, and the lubrication system is of the well-known Continental double pump type, in which one plunger pump forces oil to the timing gears in the front of the crankcase and the other forces the oil to the main engine bearings. Particular attention has been given to the size of the bearings, with a view to reducing wear to the minimum, and they are unusually liberal.

The clutch remains unchanged, and is of the dry multiple disk type, in which the 12 plates are alternately tool steel and steel faced with raybestos. This mechanism, together with the change speed gears, is enclosed in a tight housing which is firmly bolted to the crankcase of the engine with which it forms a unit, thus precluding the possibility of shafts getting out of line



Digitized by Google

and causing trouble. The change speed mechanism provides three speeds forward and reverse, and is selectively operated by means of a lever conveniently located within easy reach of the driver's right hand.



The rear axle and differential also remain practically unchanged, the drive axles being of the full-floating type and enclosed in a housing properly braced to withstand the rigors of bad-road touring. The size of the brakes has been increased from 14 to 16 inches, and by way of increasing their efficiency both sets are equalized. Proper means of adjustment is provided, and all wearing parts are equipped with liberal-sized grease cups. Both sets of brakes are located on the rear wheels and are of the internal expanding and external contracting types. The wheels are constructed with a view to the strains which they must withstand, and the spokes are unusually large in order to provide a liberal factor of safety. Tire sizes are the same both front and rear—namely, 36 x 4½ inches. The wheel base of the car has been increased from 120 to 121 inches.

Except that the wheel base is 116 inches—it was 110 inches in the previous model—and that there is a corresponding difference in size in the other component parts, the 34-40 model is practically a mechanical duplicate of the larger one. The motor, of course, is slightly smaller, though it is of the same make. Thus, the overhead valve mechanism which last year was a feature of the smaller model, has been displaced, the valves in the new engine being located all on the same side, where it is a simple matter to enclose them completely by means of a single tight cover. The bore and stroke of the engine are 4⅛ x 5½, respectively, the horsepower rating being obtained at approximately 1,000 revolutions per minute. Inasmuch as the motor is capable of giving off 42 horsepower, it may be appreciated that the rating is conservative.

The remainder of the chassis, as already has been mentioned, is much the same as the chassis of the larger model, the essential elements embracing the same multiple disk clutch, three-speed selective gear mechanism, full-floating rear axle and underhung springs. In line with the improvements which have been made and the increased equipment, the prices of both models have been increased slightly. The 44-50 in seven-passenger touring car form now lists at $2,000, which represents an increase of $200. The small tonneau and limousine have been increased in price from $1,775 and $3,000 to $1,975 and $3,050, respectively. On the smaller model the price of the touring car has been increased from $1,350 to $1,700, the roadster also listing at the latter figure.

RIGHT SIDE OF ABBOTT-DETROIT "34-40" CHASSIS

ABBOTT-DETROIT "44-50" MOTOR

Respect That Is Due the Grindstone.

The grindstone in a machine shop should be treated with more respect than it usually receives. It can be as easily ruined by lack of attention and forethought as any of the seemingly more delicate adjuncts of the shop, and unless care and consideration are exercised in the use of the device, good results cannot be expected.

A stone should never be allowed to stand with the bottom immersed in water for any length of time, for the practice will cause the lower part of the stone, which naturally is the heavier part, for they are very seldom, if ever, perfectly balanced, to become brittle and wear out more quickly than the rest. A flat spot, which will preclude the possibility of accurate grinding, will result. The stone should be wetted only when in use. The "drop by drop" method from a suspended bucket is best. In case a flat spot does develop, it can be corrected by turning down the stone, and for this purpose a piece of gas pipe is to be recommended. When the preliminary or rough cut has been taken off with the gas pipe, the application of a piece of "scratch" stone will soon put the surface in perfect working condition.

Although care should be exercised in selecting a grindstone, it is not always possible to choose one which will be absolutely free from soft spots and flaws, and this is especially true with stones of large diameter. Naturally, if the stone is harder on one side than on the other, the softer side will wear hollow, which will in time render the stone useless. The defect can be remedied, however, by the use of boiled linseed oil. The stone should be thoroughly dried and the soft side turned uppermost and brushed with oil, which will sink into the stone. The operation should be continued until the stone will absorb no more of the oil. A few days will suffice for the oil to dry, when the stone is ready for use. Flaws—that is, holes—should be filled with a mass consisting of stone-pitch (earth wax), 5 parts; tar, 1 part; powdered sandstone, 3 parts; by weight. The mass should be heated to the boiling point and stirred until thoroughly mixed. After heating the defective places in the stone by the application of red hot irons, pour the mixture until the hole is completely filled. After the filler hardens, the stone should be turned and dressed until the surface is in prime condition.

The speed at which a grindstone revolves is a point which often is neglected although such neglect oftentimes leads to serious consequences. Not only are tools liable to be "burned" on a stone which travels at too high rate, but the stone itself is liable to be torn asunder by the centrifugal force.

It is important to clean all tools and articles before grinding, carefully removing all grease, oil, etc., as the pores of the stone become clogged with these impurities, which not only considerably diminish the cutting qualities, but also impare the strength of the stone. Should one side of the stone be very much lighter than the other, the defect can be fixed by "weighting" that side with lead so that the motion of the stone will be uniform. Naturally, if the stone is firmly and truly mounted on an arbor which turns in bearings which allow very little play, "wobbling" will be prevented and better results obtained.

Goodyear to Issue Another Publication.

"No-Rim-Cut News" is the title of a monthly organ, the publication of which has been undertaken by the Goodyear Tire & Rubber Co., of Akron, O. In addition, the Goodyear company issues three other publications—"The Motorcycle Bulletin," the title of which explains itself; "The Family Newspaper," which is issued twice a month to the company's sales organization, and the "Winged-Foot Clan," a semi-monthly which is distributed among the factory employes, whose welfare and efficiency it is designed to promote.

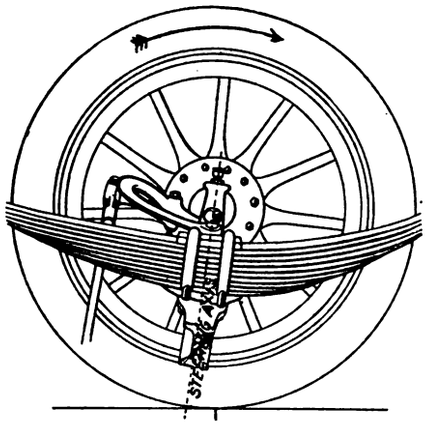
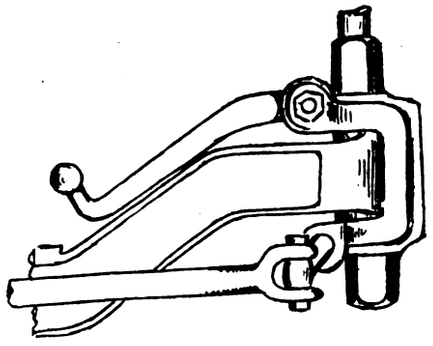
THE RELATION OF STEERING KNUCKLES TO SAFETY



The "Vital Point" in the Light of Life Insurance and the Important Part It Plays—Influence That Has Been Exerted by Experience in Altering Designs—Variety in Methods of Construction Revealed by Modern Practice.

It is doubtful if there is any one part of an automobile, or, strictly speaking, any two parts, which play a more important part than do the steering knuckles. It is true that the safety of passengers—and of pedestrians, too—depends to a great extent on the efficiency of the brakes, but it is on the steering knuckles that the greatest responsibility falls, for whereas the failure of the brakes does not necessarily jeopardize life or property in every case, provided the vehicle can be maintained on its course at the will of the driver, failure of the steering apparatus is, generally speaking, of serious consequence. On more than one occasion, the steering knuckle has been styled "the vital point," and there is every reason to believe that the designation is apt.

Breakages and their consequences are very much less in evidence now than they were in the early days of the automobile, of course, and there are any number of very good reasons why this should be so. In the first place, experience has dictated the proper size of knuckles to use, and in the second place it scarcely need be pointed out that, through the efforts of a veritable army of metallurgists, materials have improved in quality several hundred per cent. within the past few years. Incidentally, designs of the knuckles themselves, and of the connections, have in the majority of cases been improved out of all semblance to their original shapes, and in a number of notable instances, protracted experiment coupled with designing skill has resulted in the production of patterns which reduce the liability of disastrous results following the fracture of parts to a point where it is very nearly negligible.



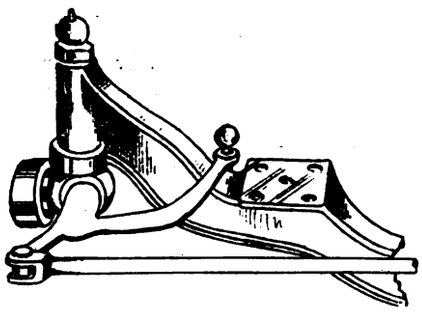
That is to say, whereas the fracture of a knuckle a few years ago virtually took the control of the car out of the driver's hands and put it into the hands of Providence, knuckles and steering connections now are made by more than one manufacturer which may be relied upon to hold the car to its course, irrespective of whether one or both of them is doing its duty in permitting the car to be guided. In other words, if one of the steering knuckles should be accidentally broken, or the tie-rod which connects them should fail, the car still would pursue its original course. Needless to add, if the knuckle which connects with the steering hand wheel were broken it would be impossible to guide the car, however.

The effect which is obtained by those manufacturers who attempt to obtain this result is styled a "caster effect" and finds its most frequent example in the caster upon which various pieces of furniture are mounted. Another familiar example is the ordinary bicycle fork. Without going deeply into the subject, which is not very deep at best, the result is obtained by locating the point of contact between the wheel and the road just back of the steering axis. The effect is that the steering wheels virtually "trail," and of course maintain the vehicle in the same path it was traversing prior to breakage of the steering knuckle.

CASTER EFFECT ILLUSTRATED

Notable among those manufacturers who obtain this caster effect with their products is the Timken-Detroit Axle Co., of Detroit, the theory as applied by this company being illustrated in the accompanying sketch. Strange as it may seem, the accomplishment of the result necessitates no radical alteration in design or construction of the axle or steering connections. Instead, it necessitates merely that the steering yoke be tilted backward slightly. The easiest way to do this is to employ spring pads that are slightly thicker at one end than they are at the other, and this is the method that is used by a large number of car manufacturers whose products are Timken-equipped.

B. & S. CASTER

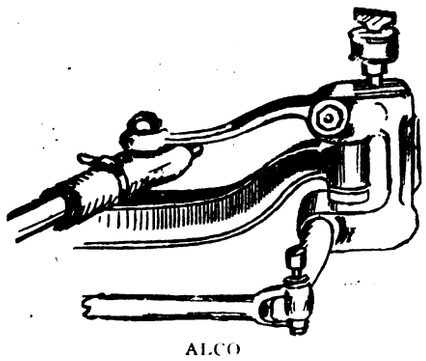


In the products of the B & L Caster Axle Co. of Chicago, the title of the company indicating that the caster effect has been made a cause of construction rather than an effect, the accomplishment of this feature has been sought after in a very much more elaborate manner, the construction of the steering knuckle, which is one of the very few that are of the reversed Elliot type, being illustrated herewith. In this construction, the axle penetrates three-eighths of an inch forward of the spindle center, thus throwing the point of contact between the road and the wheel that distance behind the steering axis. The effect is that the front wheels will continue in the same direction they are pushed by the rear wheels unless their direction is purposely changed by the driver. Incidentally, the construction of this particular axle is such that the turning point is in the center of the wheel, which throws the load more directly on the bearing center.

But, as has been explained, though a great many manufacturers take advantage of this caster effect, or make a point of obtaining it, there still remains a great number whose chief reliance is placed upon the excellence of their steering knuckles and connections and who make no attempt to obtain a caster effect, even when it requires merely that the existing type of spring pads be replaced by others of tapering form. Their faith in thus relying on the strength of materials is justified, of course, by the comparative scarceness of steering knuckle troubles.

This does not alter the fact, however, that there must of necessity be a tremendous strain on this portion of any car, nor does it remove any of the responsibility from the parts themselves. Added to the strain imposed on the parts when the wheels are turned—it varies from practically nothing when the car is traveling fairly rapidly to an amount that is unsuspected when the car is standing idle, and it becomes necessary to turn the wheels before the car can be moved, as in a garage, for instance—there is the strain of the sudden jar and jolt caused by one or the other of the wheels passing over an obstruction in the road or dropping into a hole. It is

Digitized by Google

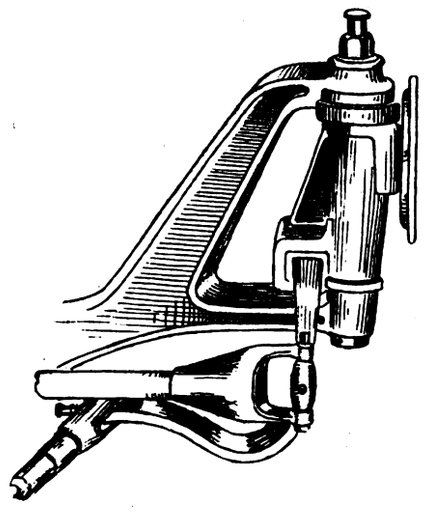


practically impossible to measure these stresses, and the only logical course to pursue is to allow a liberal factor of safety in designing. Needless to add, this is common practice. Still, exceptionally large steering knuckles may not necessarily indicate great strength. A few years ago, no inconsiderable number of prospective purchasers of cars were in the habit of judging of a car's worth by the size of its steering knuckles almost as much as by anything else. To-day, however, it is different, for it is realized that mere size is no

MITCHELL

indication of ability to withstand punishment.

Another factor which must be reckoned with in the design of steering knuckles—and, indeed, in the design of every other part which is under constant strain—is the vibration that is caused by the passage of the car over the roads. It is only in comparatively recent times that the effect of constant vibration in crystallizing steel has been noted. As an indication of the effective manner in which science, assisted by, or in the garb of, sport, has wrestled

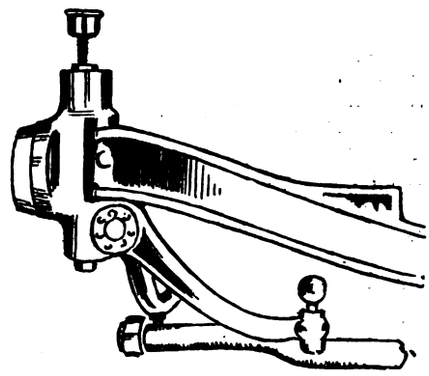


ALCO

with the problem, the experience of some of the cars in the two last long distance races on the Indianapolis Speedway might be cited. Last year three of the cars in the race were retired with broken steering knuckles. In two of these cases it was given out that the cause of the trouble had been crystallization. This year, though cars of the same make were driven by the same drivers, there was not a single instance of the kind. Though it may have been coincidence, which is unlikely in view of the fact that the average speed of nearly all the cars was greater, it is much more likely that manufacturers profited by their previous experience to redesign their steering knuckles, or at least to make them of even better materials.

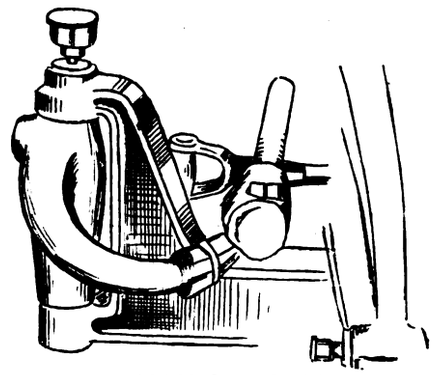
As regards the various parts that go to make up a steering gear complete, practically the same confusion of nomenclature obtains, as it is noticeable in connection with other parts. Consequently it may not be irrelevant to point out that the tie-rod is the rod which connects the steering arms on both knuckles; the reach rod is the one which connects the steering hand wheel with the tie-rod through the intermediary of one of the steering arms. The words steering arm, of course, will be understood to mean the projection from the knuckle to which the tie-rod is attached and which serves to turn the wheels.

In the majority of cases a position behind the front axle is favored for the location of the tie rod. In a few cases, the tie-rod is placed in front of the axle, though in general it is believed that the rod is less liable to accidental damage when placed in



RENAULT

the less conspicuous position. The worst that could happen to the rod would be its fracture, due to accidental collision with a projection in the road, and though trouble of this kind scarcely would require very energetic hunting, it would be less likely if the rod were placed behind the axle.



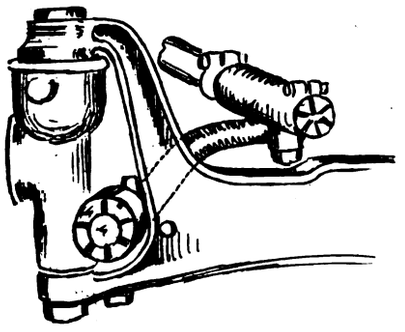
Less serious trouble, of course, involves the accidental bending of the tie-rod, and this trouble is a great deal more prevalent than generally may be supposed. It may or may not seriously impair the ease with which the vehicle may be steered, but in any case it indicates its presence by the condition of the tires in a shorter or a longer period of time, corresponding to how little or how much the rod is bent. When the rod is bent, it naturally causes the wheels to "toe" in or out, according to whether its position is in front of the axle or behind it, and instead of rolling smoothly over the road they scrape along partly sidewise, the immediate effect being the elimination of the tread on the tires.

For much the same reason—namely, to prevent it from accidental injury due to obstructions in the roadway—the reach rod also is placed high in the majority of cases and the principal steering knuckle is arranged over the front axle. The proper protection of the reach rod is perhaps of even greater importance than the protection of the tie rod, for, as has been explained, in case of fracture of the latter it sometimes is possible to steer the vehicle by reason of a caster action. But where

PIERCE-ARROW

the reach rod or the principal steering arm is broken, the control of the car is lost. Incidentally, by placing the rod as high as possible and the steering arm over the front axle the danger of these parts coming into contact with road obstructions with just sufficient force to change the direction of the car without breaking the parts also is removed. In this respect, it should be remembered that even a momentary change of direction when a car is moving at high speed may be sufficient to

COLUMBIA-KNIGHT

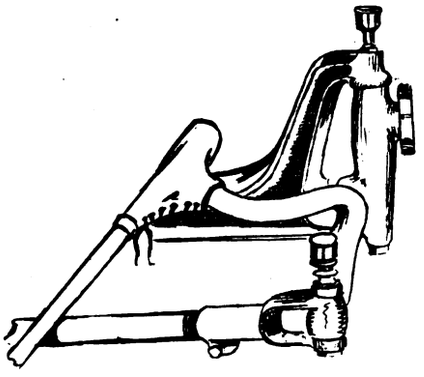


run it into a ditch or into another car, the speed of the car itself determining the number of feet it will traverse in a given time for a known deflection of the road wheels.

The general practice with regard to the construction of these two rods is to provide some means of lengthening or shortening them a certain amount in order to compensate, temporarily or permanently, for slight disalignment of the wheels caused by either bent steering arms or a bent tie rod. Where such means of adjustment is provided it is a simple matter, of course, to line the wheels up temporarily on the

Digitized by Google

road if the tie rod becomes bent. It is the precaution of the wise motorist to test the alignment of the wheels occasionally, especially when touring in rough country. And it is equally wise to remove a bent tie rod and straighten it at the first opportunity if the advantage of being able to make adjustments at some future time is to be felt.

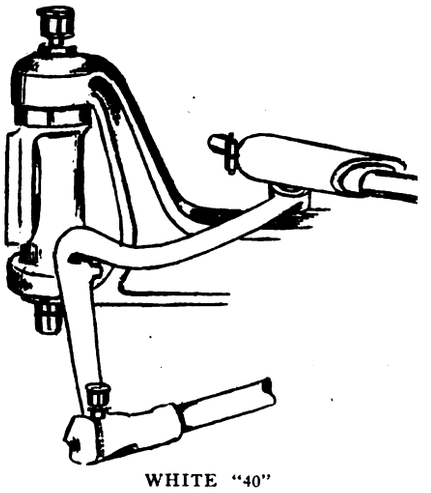


There are three general types of steering knuckles in use, the Elliott type, which is by far the most popular and is employed by

KNOX

at least 90 per cent. of all manufacturers; the reversed Elliott type, and the Lemoine type, the latter two having but few exponents.

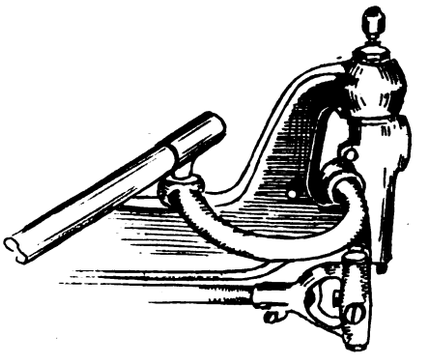
Among the better known cars in which the Lemoine type of steering knuckle is employed is the Mitchell, the design, as developed by the Mitchell-Lewis Motor Co. being illustrated herewith. The view shows the axle and steering knuckle from the back, and as may be seen, the tie rod is located behind the axle with the steering



BUICK

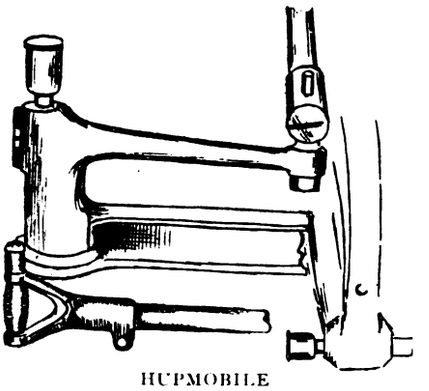
arm above it, where it is thoroughly protected from accidental injury. The design is distinctive and differs from all the others in that the axle end is a solid forging drilled vertically. The spindle is formed integral with the steering arm and is inserted through the vertical hole from the bottom.

Alco cars are among the very few in which the reversed Elliott form of steering knuckles are used, the design being distinctive for this reason and also for its particularly rugged construction. The reversed Elliott type differs from the Elliott type in that the axle is inserted in the yoke which is formed by the knuckle. This portion of the axle in the case of the Elliott type forms the yoke which receives the spindle between its ends. In the Alco cars, also, the steering arm is located above the axle, though the construction differs from the others in that the arm proper is not forged integral with the knuckle proper, but is a separate forging which afterward is bolted in place, the method of construction having the advantage that it avoids the simultaneous forging of the comparatively heavy knuckle and the lighter projecting arms. The Pierce-Arrow car is another in which the reversed Elliott type of knuckles is used, and though the principle is the same, the construction is quite different, as may be seen by comparing the pictures. In the Pierce-Arrow car, for instance, the steering arm is located below the axle instead of over it, though it is protected by the location of the tie rod. Here, too, the steering arm is a separate forging which afterward is bolted firmly in place.



As a matter of fact, this method of construction is fairly common, though it is

WHITE "40"



not quite as common as the method in which the knuckle and all its parts are made integral. In Stutz cars there is another example of this method, the steering arm, as shown by the picture, being separate and coming above the axle. The tie rod is located behind the axle, the knuckle itself being of the Elliott type. Knox practice reveals construction that is quite similar, the knuckle being of the Elliott type with the steering arm located above the axle with the tie rod in a protected position behind it. Foreign practice differs but little from American with regard to the design of steering connections, Renault construction, which is typical of French and other European design, revealing the Elliott knuckle with the steering arm and tie rod located behind the axle. The steering arm in this case is perfectly straight and is a separate forging bolted to the knuckle, the principal point of variance being in the location of the reach rod which is placed below the tie rod.

In the lighter and lower priced cars the method of forming the knuckle and the steering arms integral with the steering knuckle generally is the order, for it simplifies construction and assembling and reduces somewhat the number of parts involved. This arrangement of the parts does not necessitate any particular location of either steering arms or reach or tie rods, of course. In the Buick and White "40" arrangements, for instance, the tie rod is placed behind the axle with the steering arm above the axle, the construction being

STUTZ

quite similar in both cases. In the Hupmobile arrangement, however, the steering arm is over the axle, with which it is parallel when the wheels are not deflected, and the tie rod is in front of the axle and below it. Still another variation is found in the Columbia-Knight cars, though the knuckle is of the Elliott type with the steering arms integral. Here, though the steering arm is located above the axle, it also is in front of it, the location being best made plain with the aid of the picture. The

HUPMOBILE

tie rod in this case is placed behind the axle and as high up as the proximity of the frame will permit.

In making the connection between the steering arm and the reach rod, it is the invariable practice to form the end of the steering arm into a ball which fits into a socket in the reach rod. By way of reducing the amount of road shock transmitted to the driver through the steering wheel, and also to relieve the parts of some of the strain imposed by road vibration and the jars and jolts which are caused by the wheels passing over obstructions, the ball at the end of the steering arm is cushioned

Digitized by Google

between two helical springs, the whole usually being enclosed in a leather boot which serves the purpose of retaining the lubricant and at the same time excluding dust and dirt.

The construction quite naturally permits a certain flexibility in control which is not obtainable otherwise, and thereby reduces the strain on the driver by no uncertain amount. Incidentally, it results in a certain amount of lost motion between the steering wheel and the road wheels, and though it is so small as to be negligible, it nevertheless opens up an interesting question which, on more than one occasion, has been the cause of discussion.

It is held by some manufacturers that for the best all around results—that is to say, the easiest steering and the least wear on tires—the front wheels should be lined up absolutely parallel. It is held by others, however, that the best results are not produced unless the wheels are turned in slightly, the amount varying from one-quarter to three-eighths of an inch. And though it would seem that there is little excuse for turning the wheels in, that it undoubtedly would cause excessive tire wear, there really is reason in the method. For instance, experience tends to prove that with ordinary construction the wheels of a car will spread outward immediately the tie rod is removed or broken. To those who have had opportunity to witness an accident of this kind, or who have been unfortunate enough to be concerned in one, the phenomenon should be perfectly plain. Suffice to say, the result is substantially as stated—that is, the wheels almost invariably turn outward, though just why this should be it is difficult to explain.

It is pointed out by some that it is one of the effects of road vibration which causes the wheels to turn outward, and it is on this theory that the wheels are set so that they are closer in the front than they are in the back by about one-quarter of an inch. The primary reason for setting them this way, of course, is the lost motion which must almost of necessity be present in the steering connections. Thus, if they are slightly closer together at the front and the road shocks tend to cause them to fly outward, their movement to the limit of the lost motion will bring them parallel. Other manufacturers who set their wheels parallel in the first place scoff at the explanation and contend that there is, or ought to be, just as much tendency for the wheels to turn inward under the influence of road shocks, and for this reason the expedient of setting them to turn inward a fraction of an inch is ignored.

However, this is one of the problems to which the future may bring a solution, and though it is a minor one at best and one which need cause very little loss of sleep for the reason that either method of setting the wheels is equally effective, the fact remains that it hedges on an unanswered question—it is one of the few unanswered questions, however, and it is a matter of opinion whether the game of searching for the answer is worth the candle.

Rajah Evolves Engine-Starting Plug.

To complete its line of Rajah spark plugs, which now comprises plugs of all sizes for both pleasure and commercial car use, the Rajah Auto Supply Co., of Bloomfield, N. J., just has placed on the market the engine starting plug shown in the picture. Those parts of the plug which have to do with the sparking, the steel shell, imported porcelain, knife edge bushing and central wire electrode, are of usual Rajah construction. Held fast to shoulder on the steel shell by means of a jam nut, however, is a hollow yoke which serves to carry the mixture to be introduced into the cylinder to a passage drilled through the steel shell. Above and below the yoke are

copper-asbestos gaskets, which prevent the escape of the gas. The gas is conducted through the center of the plug, and passes all around the spark gap so that firing, practically, is certain. The application of the starting attachment, however, in no way impairs the facility with which the plug can be taken apart and cleaned, and the operation can be completed without disarranging the gas piping.

Detector Shoots Numbers After Accident.

Necessity is said to be the mother of invention, and if such be true that dear old lady has a varied and wonderful array of offspring, ranging from devices to prevent earthquakes to simple little instruments which may be carried in the pocket and whose uses are legion; but Oscar Weissenborn, formerly president of the Berkeley Club, in Hudson City, N. J., has added one to Old Lady Necessity's children which, aside from any necessity for the device, is fully as wonderful as any. It is a detector for the car of the man who runs down a pedestrian and then seeks to escape. Bows and arrows are generally associated with the little summer-clad God of Love, but there is little inkling of love in the Weissenborn device, although the bow principle appears. There is a bow arrangement at the front, the bow being held back by a string so that when the car strikes anyone the string is broken and the bow shoots—not arrows, but a handful of the car's number plates, thus scattering over the roadway a whole hatful of clues to the identity of the machine. Legislation is all that is needed to bring the device into use and bring riches to the inventor—and legislation usually is difficult.

Use Cheap Fuel to Test Their Cars.

Because there are several grades of "petrol" or "motor spirit" on sale in London, and because they vary considerably in quality the manufacturers of Siddeley-Deasy cars have hit upon the novel scheme of employing the lowest grade in testing their cars before final delivery. The grade that is used is the same as is supplied to taxicab and motor bus companies, whose cars are equipped to operate on benzol, if necessary and is styled "Pratt's taxi-bus motor spirit." The reason for the innovation, is it explained, is to demonstrate that the cars can be run efficiently on this and other low grade fuels, and thus to set at rest any fears regarding their operation on cheap fuel, which might be engendered in the minds of prospective purchasers of cars.

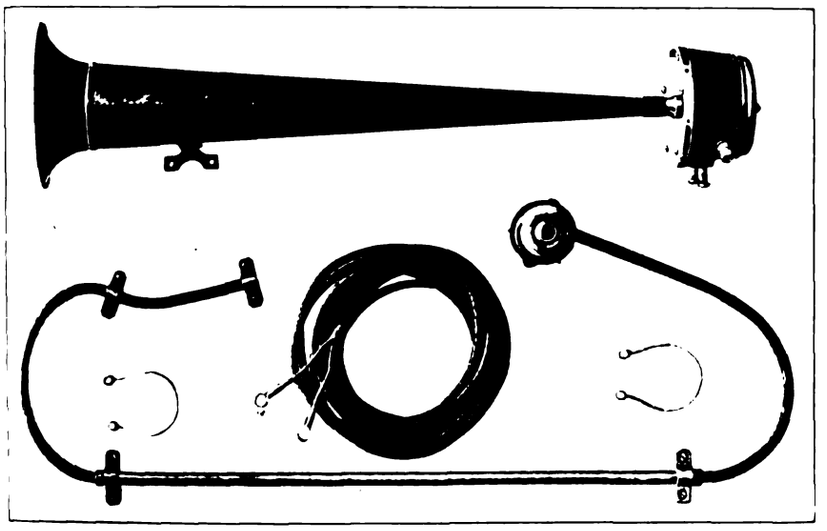
Truck Floors that Require Caulking.

The floors of motor trucks which are used for such service as carting ice, ice cream, or commodities which are in liquid form and liable to "slop over" should be caulked so as to prevent in so far as possible, the mixtures from reaching the gear set, clutch, propeller shaft, etc. Before the seams are caulked, however, a priming coat of paint should be applied to the seams and allowed to dry, otherwise the water which is retained in the oakum or cotton which is used to fill the cracks will cause rapid deterioration. The planks should be perfectly dry before the seams are caulked, so that when they become moist and swell perfectly tight seams in the truck floor will result.

Unwise Use of Air Compressors.

Although there may be no particular danger of blowing up compressed air reservoirs such as are used for tire inflation or engine starting purposes, due to the fact that almost invariably they are equipped with some sort of a safety valve to prevent such contingencies, it is unwise for obvious reasons to permit an air compressor to run for a greater length of time than is necessary to obtain the desired pressure. In the first place, it causes the pump to heat up excessively, and in the second place it causes an amount of wear that decreases the life of the pump proportionately.

Care With the Blow-Torch on Aluminum.



The melting point of aluminum is quite low, and for this reason it is necessary to exercise care when using a gasolene blow-torch or other source of extreme heat on aluminum parts, especially if they are rather thin, to avoid melting through the soft metal.

RECONDITE MEANING IN "MAXEFF"

Name of Horn Is Clever Combination of Abbreviations—New Electric Product and How It Operates.

Ever since the organization of the Maxeff Electric Horn Co., of 814 Woodward avenue, Detroit, Mich., several months ago, it has been generally supposed that the cryptic Maxeff represented a combination of some of the letters of the organizers' several names. It transpires, however, that such is not the case. In choosing the distinctive name, the manufacturer has intended to indicate by its letters that the horn has been designed to realize maximum efficiency both as to wearing qualities and and to tone volume and clarity. As originally developed, the Maxeff horn resembled in shape the orthodox type of bulb horn and was intended primarily for outside location. Since then, however, another type has been developed in response to a demand for a light, compact, and above all, efficient type of electric signal horn which may be located under an engine's hood as standard equipment.

MAXEFF UNDER-HOOD TYPE OF ELECTRIC SIGNAL

It is on the different construction of the horn and its scientifically determined design that the manufacturers base their claims of superiority over other electric horns of the same general type. By reason of the arrangement of the component parts, arcing and pounding at the contact points has been eliminated thus effectually doing away with one of the more or less common sources of trouble to which horns of this type fall heir. Incidentally, as the pounding is done away with, the method being one of the horn's patented features, wear in the parts is proportionately decreased. Laying emphasis on the efficiency of the horn, which produces a deep-toned note not unlike that of a bulb horn, the current consumption at six volts is but .07 of an ampere. The reason for the low current consumption is explained by the mechanical arrangement of the parts, which is such that in the down stroke of the armature and hammering pin no retractile springs are used to work against the magnetic pull. This is another of the features upon which patents have been allowed. Another of the features which increases the strength of the note produced and accounts in no small measure for the small amount of current necessary to operate the horn is that the diaphragm is not punctured as commonly is the case with horns of this type. The tonal quality of the sound produced is accentuated by reason of the shape of the sound chamber which is carefully proportioned in size and shape to the size of the diaphragm. Giving

MAXEFF BULB-TYPE SIGNAL

evidence of the thoroughness with which the whole problem has been attacked, in the search for maximum efficiency, care in designing has been carried even to the wiring, which is arranged to be carried in a metal tube. In explanation of this feature, it is pointed out that in matters of details of equipment much of the difficulty experienced with electric signals can be traced directly to the wiring, and it is hoped by thus enclosing it so that there can be no possibility of its becoming accidentally deranged or worn so as to cause short circuits effectually to remove the cause of trouble.

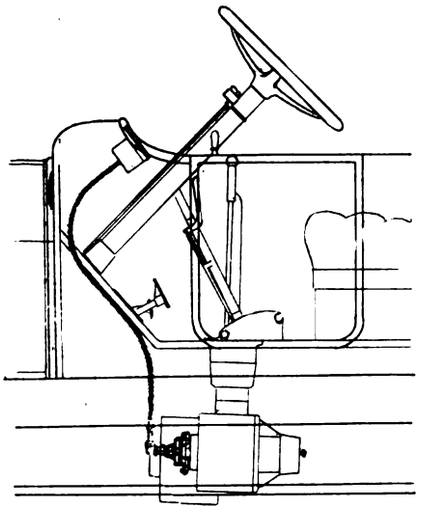
Why Electric Systems Need "Exercise."

That storage batteries which are but partially discharged and then fully charged again, the cycle being often repeated, will in time lose their capacity is an established fact. With most of the electric lighting and electric engine starters now on the market, however, the condition of full discharge is very seldom approximated, since the dynamo is continually charging the battery during the daytime, and is carrying the light load at night when the car is in operation, so that the batteries are nearly always fully charged. Only when the motor is inoperative and the lights are burning, or for that fraction of a second when the engine starter is in operation, are the batteries called upon to furnish any appreciable amount of current. Obviously the batteries are not operating under the best of conditions to insure long life.

H. J. Murch, of Worcester, Mass., who owns a Cadillac car fitted with a Delco electric starter which also serves to furnish the current for lights, has devised a plan which not only provides the battery with the proper amount of "exercise" to keep it in first class trim, but which also puts to use the extra current generated by the dynamo. On the dash of his car Murch has placed a pair of sockets arranged to accept two "jack" plugs attached to flexible electric light wires which, in turn, are connected to the house lighting mains. On "plugging in" each evening, when he lays up the car, the owner can call upon the batteries to furnish sufficient current to light five 16-candle-power lamps, used for house illumination.

To Prevent Escape of Acetylene Gas.

Not only are leaky acetylene gas pipes a source of danger, but they are a constant source of waste, for each ounce which escapes naturally reduces the supply of gas just so much. Too much care, therefore, cannot be taken in examining the rubber hose connections, which should be replaced at least a couple of times during a season. The copper tubing, too, should be tested at least once every season, especial care being directed toward the elimination of cracks at the joints and bends. As is the case with the gasolene supply pipe, a loop will obviate much trouble. That few motorists pay any great amount of attention to the condition of the lighting system recently was demonstrated at one of the Prest-O-Lite service stations, when in the piping of 40 cars tested 22 were leaking.



The ball check valves which control the movement of oil through the pump where pressure feed lubrication is adhered to, should be cleaned occasionally to insure proper working.

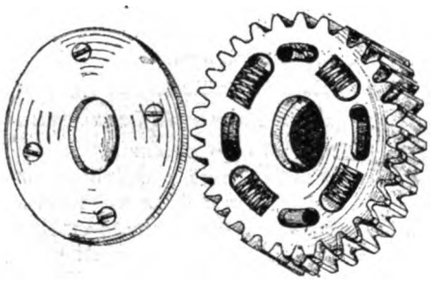
Speedometer Drive That Is Unusual.

Taking its cue from the generally noisy and otherwise inefficient speedometer-drive methods that prevail in a great many cases, the Knox Automobile Co., of Springfield, Mass., has developed a new method of driving that necessary adjunct. It is calculated to eliminate at once not only the noise which usually emanates from the generally loose-fitting and rapidly-rotating gears, but to get further back into the trouble and eliminate the first cause of the noise, which, briefly, may be summed up in the one word "wear."

In the ordinary unprotected position on one of the front wheels, it is an undisputed fact that the gears accumulate more or less mud and road dirt, the immediate effect of which is to cause wear. It follows that if the mud is of the clay-like and clinging variety its effect is to force the

gears out of mesh when the accuracy of the speed indicating instrument becomes to all intents and purposes nil. In the new Knox method, the driving gear is arranged on an extension of the lay shaft of the change gear mechanism, as shown in the accompanying sketch, and as it is thoroughly protected by the underpan, accumulations of foreign matter in an amount sufficient to impair its proper working are impossible.



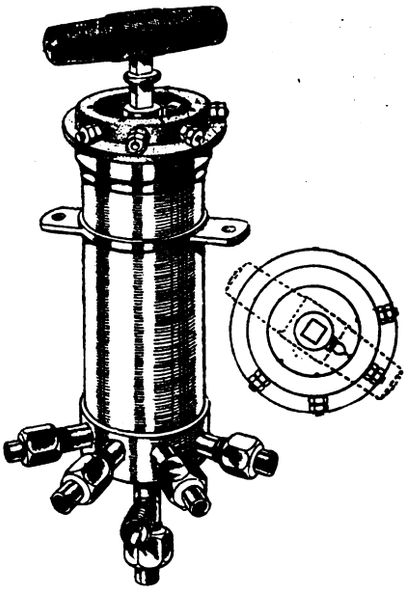
Incidentally, the flexible driving shaft is considerably shorter, and even though this portion seldom, if ever, gives trouble, the likelihood of the contingency is proportionately decreased. Another of the important advantages of the method of drive is that no amount of wheel bouncing, as when the car is being driven rapidly over very rough roads, can affect the speedometer reading by causing oscillations of the dial hand. The instrument itself is located in an extension of the cowl dash after the manner that has been originated at the Knox factory, and is in plain sight of the driver at all times.

Removing the End of Broken Tap.

The removal of the end of a tap which has broken off short in the work is a patience trying job. Where the proper size of tap for the hole has been used, and the operation has not been pushed too rapidly, the stub can be removed with a pair of tweezers. The hole should be thoroughly cleaned with kerosene squirted from a gun to remove all chips of the metal, and the tweezers, which should be as large as the work in hand will permit, should be applied to the hollows of the tap and the latter carefully worked to and fro until quite loose.

To Prevent Noise in Timing Gears.

Probably no part of the motor has occasioned more thought and experiment with regard to the elimination of noise, than the



timing gear, and though much ingenuity has been brought to bear and many modifications have been made in existing devices, all of which have been directed toward the production of a silent valve gear, the efforts of designers have not ceased, despite improvements that have been effected. Much of the progress has consisted of enclosing the valve tappets and appendages in a chamber which serves not to eliminate the noise but merely to muffle it. But as it is only after a motor has been run for a sufficient length of time to allow wear to throw the various parts out of proper relation for the maintenance of silence, it is plain that not all of the improvement is real or lasting improvement.

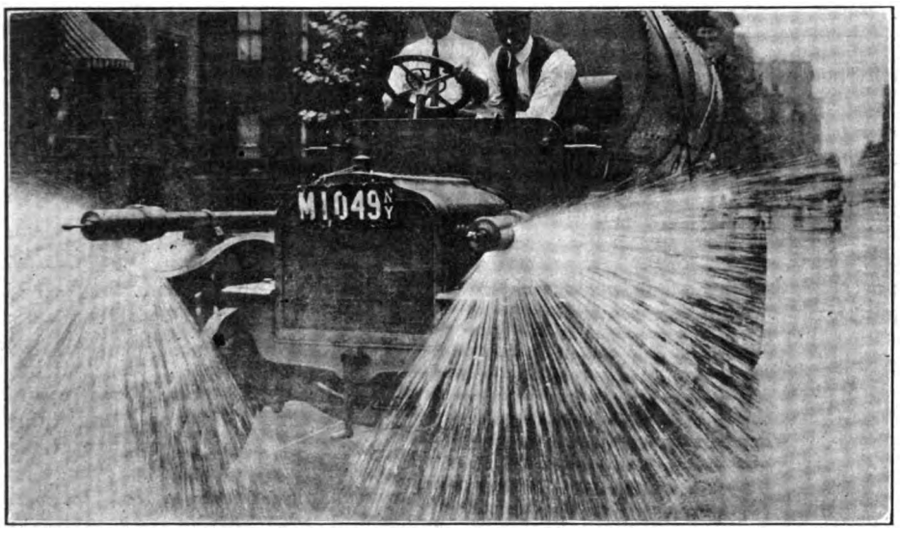
With the idea of eliminating the noise caused by the clashing of the teeth of the timing gears, even after considerable wear has been occasioned by use, the arrangement shown in the accompanying illustration has been evolved abroad by the Hispano-Suiza Co., which is incorporated, and it is claimed that success to an unlooked for degree attends this Hispano-Suiza product. The device consists of two pinions of the same diameter but with different face widths, which are mounted concentrically on the crankshaft. Into pockets which are formed in the body of the pinion of smaller face which is not keyed to the shaft are placed four helical springs, which bear against four lugs, which protrude into the pockets from the body of the keyed pinion The springs serve to keep the movable pinion in such a position that the teeth always are slightly in advance of the teeth of the stationary pinion—with regard to the crankshaft—and thus the slight movement of the pinions with relation to one another compensates for any wear.

British Idea of Acetylene Starter.

Although America generally is conceded to be the home of the ignition type of motor starter, it is doubtful if even in America can be found a device of the kind bristling with such unusual features as characterize the Ashford starter, recently introduced by Ashford & Greenshields, of Lancaster, England. The most startling of the features are an electric "tell-tale," which is designed to indicate the cylinder that is on the firing stroke, and a rotary distributing valve, which is operated through the pump handle. The electric indicator, as the illustration shows, takes the form of a ring made of fibre which surrounds the pump barrel and which is provided with a terminal screw for each cylinder of the motor. A wire leads from the spark plug of each cylinder to one of

the terminals, so that a spark will jump across the gap formed between the terminal and a pointer on the pump rod when the pump handle is turned around so that the pointer is opposite the terminal corresponding to the cylinder which is on the point of firing. At the same time, the distributing valve, which is positioned in the base of the pump, opens communication with the same cylinder and closes off the other leads so that the charge is introduced only into the cylinder which is on the firing stroke. Carburetted cold air is used as a fuel, the attainment of a rich mixture even in cold weather being insured by a priming device on the pump, so that small quantities of liquid gasolene can be introduced if need be.

Slots that Give "Bite" to Screwdrivers.



A screwdriver ground to the usual shape is not always effective on round-headed screws, for it is liable to slide out of the crack before the screw can be started. If, however, a small slot is filed on either side of the end of the driver, the device will get a better "bite" on the screw head.

SPRINKLER SPRINKLES OWN PATH

Municipal Vehicle Designed for Indianapolis Has Sprayers at Front—Distributes Water Under Pump Pressure.

The problem of laying the dust which arises from dirt or macadam roadways is one which those interested in municipal welfare still have "under the microscope," and though dry treatment with calcium chloride, and treatment with gas tars and crude petroleum products are found to give excellent results, both are in the end more costly than the daily sprinkling with plain water. Thus it happens that innovations in "sprinkling carts" always are interesting to municipal engineers, especially if the innovative side is directed toward cutting down expense, or — which really amounts to the same thing in the long run—increasing the area which can be sprinkled in a given time. The sprinkler shown by the photograph was designed for that purpose by the International Motors Co.; it was built for the street cleaning department of Indianapolis, but last week was tried out in New York prior to shipment to the Hoosier city.

SAURER "DUSTLESS" FORCE-FEED STREET SPRINKLER

The sprinkling apparatus is mounted on a 6½-ton Saurer chassis of standard construction. The riveted tank, which is 4½ feet in diameter and has a capacity of 1,400 gallons, is mounted on a cradle and "guyed" with cross stays provided with turn buckles, so that shifting is impossible. The most novel features of the device, however, are the double acting force pump, which, driven by the motor, forces the water through the nozzles, and the location of the nozzles themselves, about a foot in advance and on either side of the motor hood. This location was adopted so that the truck itself would not cause the very evil it is designed to cure; the forward position of the spraying apparatus wets down the street in advance of the wheels, so a cloud of dust is not raised as a preliminary to the dust-laying.

The nozzles are made adjustable between wide limits, so that the quantity of water thrown out and the distance to which it is thrown can be regulated by the driver to suit the conditions. Obviously, with a pump maintaining a constant pressure, the water can be sprinkled over a much wider stretch of roadway than would be possible were the water permitted to flow out by gravity, and the areas sprinkled can be maintained constant until the last drop is out of the tank, whereas with the gravity feed, the area naturally diminishes with the loss of head in the tank. It is claimed that a roadway from 70 to 80 feet wide can be sprinkled at one operation, and at a rate of well over 10 miles an hour, which naturally is quite beyond the scope of the horse-drawn sprinkler.

University to Confer "A. E." Degree.

Although automobile schools or "chauffeur factories" where instruction in the driving and operation of motor cars is dispensed are so common as to be almost regrettable and though several colleges have undertaken more technical instruction, the University of Southern California is preparing to go further than any of them. A department devoted exclusively to automobile instruction, which will cover not only the operation of the vehicle but all the little as well as the important points in motor car design and construction, has been instituted in the university, Stanley Smith, C. E., and Earle Y. Boothe, M. E., occupying the chairs. They are now busily engaged in mapping out a curriculum to be covered in the two years devoted to the course. Graduates, both male and female, for the U. S. C. is a "co-ed" college, will receive a degree stamped "A. E.," which will signify that at least four years have been spent in preliminary technical study.

DISCUSSES TIRE-MAKING METHODS

Goodyear's Factory Manager Interestingly Deals With the Subject—Processes Employed and Results Obtained.

"The question, 'Which is the best type of automobile tire?' long has been a subject for discussion, and probably never will be settled to the satisfaction of everyone," says P. W. Litchfield, factory manager of the Goodyear Tire & Rubber Co., Akron, Ohio, in dealing with the matter, "but the fact that a tire has a molded or a wrapped tread does not make it good or bad, as a properly compounded or properly vulcanized tire by either process will be better than one improperly vulcanized by the other method.

"There are three prominent types of automobile tires — the one-cure wrapped tread, the one-cure molded, and the double-cure wrapped tread.

"The one-cure wrapped tread process is building the complete tire upon a core, pressing two metal side-flanges against each side of the tire up to the point known as the tread, then cross-wrapping the whole thing with strips of cloth, putting it into a heater and vulcanizing.

"In the one-cure molded type, the complete tire is built upon a core, put into a full mold, and then put into a press or heater and vulcanized.

"In the double-cure tire, the carcass is made upon the core, which is then put into a full mold and partly vulcanized. After this has been accomplished, the tread is applied to the carcass and the vulcanization completed.

"The double-cure tires are made in two ways: First, after the carcass has been semi-cured, the tread is applied to the carcass before the carcass is removed from the core. It is then wrapped and the vulcanization finished. The Goodyear Tire & Rubber Co. process, however, is exclusive, in that the semi-cured carcass is removed from the core, the tread applied, then inflated upon a rim with an air bag inside, wrapped and vulcanized. This Goodyear process insures the completion of the vulcanization of the tire in exactly the same shape which it will have when in use, equalizing all the strains in the fabric, and reducing the possibility of fabric breaks and blowouts.

"The disadvantages of the one-cure wrapped tread process are that the fabric is not thoroughly impregnated with rubber, that there is not sufficient pressure for proper vulcanization, and the tire tends to separate and disintegrate prematurely. This can be overcome to some extent by using the highest possible quality of material.

"In common practice, however, this process is usually employed by makers of unguaranteed tires, or low quality tires, in

Digitized by Google

which the defects of this process are emphasized.

"The second or full molded type of tire is the cheapest method, from the standpoint of first cost, where the workmen are sufficiently skilled to avoid fabric buckles and pinches. Its disadvantages are that the thin side walls and thick treads are subjected to the same heat for the same length of time and that the fabric and friction on the side walls are cured more than the fabric and friction on the tread, the most under-cured portion of the whole tire being where the tread united with the carcass in the center. This tends to cause tread separation and fabric disintegration long before the tread has worn out, the consumer thinking he has a good tire one day and having it go to pieces the next. In other words, it is not a well balanced tire. Also, this process has the disadvantage that in case there is any fabric pinching or buckling, it is not apparent to the inspector, and large quantities of tires are liable to be manufactured before the defect is discovered. In many cases, the first knowledge of the defect comes to light when the tire is returned for replacement.

"The third, or double-cure wrapped tread, process is the highest in cost manufacture, requires more labor, more time, more equipment, and more material in the tire. It has the advantage, however, of curing the carcass the same in all portions, the thickness of the wall being the same all the way round; it thoroughly impregnates the fabric with rubber, preventing separation; it shows any defect in the construction immediately, so that the faults can be quickly corrected, and no seconds slip through as firsts; the carcass and tread can both be made properly and the tire perfectly balanced."

Ingredients of a Fireproof Paint.

As a matter of precaution, no other than fireproof paint should be used in or around a garage. A good paint of the kind which is lasting and durable when applied to wood and which will materially lengthen the time necessary for the wood to catch fire, is made of the following ingredients taken by weight: Powdered asbestos, 40 parts; aluminate of soda, 10 parts; lime, 10 parts; silicate of soda, 30 parts, and enough non-resinous coloring matter to obtain the desired shade. The ingredients should be thoroughly mixed with sufficient water to make the application easy. Two coats should be applied.

Rubber Matting Destroyed by Oil.

Because rubber is used in the form of floor covering instead of tires, it does not follow that it is immune from the effects of oil. Many rubber mats are destroyed by oil which drips on them and is not removed. A piece of waste or rag dipped in gasolene will remove the oil thoroughly, if the bulk of it first is removed with dry waste. While gasolene is a solvent for rubber, it evaporates quickly.

AUTOMOBILE AS ALUMINUM'S AID

Franklin Company's Metallurgist Discusses Relations of This Metal to Motor Car Industry—Origin and Uses.

"The development of the aluminum industry is contemporary with the development and growth of the automobile industry," says J. H. Nead, metallurgist of the H. H. Franklin Mfg. Co., of Syracuse, N. Y. "One might say that it is perhaps due to the impetus caused by the demand created by the automobile industry for a light, strong metal that the rapid advance in the commercial production of aluminum has been made.

"Aluminum is one of the most abundant elements in the earth's crust. It is a component part of all clays and of much of the rocky structure of the earth. It is known to all as a light metal of a silver white color, which has a marked resistance to oxidation and nearly all corroding actions. The melting point is 1,215 degrees Fahr. This melting temperature makes it a fairly easy metal to melt for foundry purposes. Aluminum has a specific gravity of practically two and six-tenths or about one-third that of steel. This makes it the lightest of all commercial metals and to this property is due a majority of its numerous applications.

"The strength of ordinary aluminum in bar form is about thirty thousand pounds per square inch. Bar aluminum castings will generally show a strength of about 12,000-14,000 pounds per square inch, but for casting purposes bar aluminum is seldom used but rather one of the very valuable aluminum alloys.

"Aluminum unites quite readily with most of the common metals except lead. One of its most useful and important alloys is formed with copper and is widely used for casting purposes for automobile work. When cast it has a strength of about twenty-two thousand pounds per square inch. It is very resistent to repeated strains and will maintain its strength very well at slightly increased temperature.

"Because of these two properties, it is admirably suited for such services as engine bases and crank cases.

"The automobile manufacturers create a demand for aluminum in the customary commercial shapes, such as rods, sheets, wire, etc. Sheet aluminum is an admirable material for automobile bodies. In addition to its lightness it will not rust, is very easily worked and takes a very excellent finish.

"The builders of the Franklin have been in the foreground of manufacturers who have recognized the advantages of aluminum. The Franklin car is one of the lightest built and aluminum is used freely in its construction.

"The Franklin body is made of sheet aluminum, the base of the engine is aluminum, as is the carburetter body and the transmission gear case. These are the big parts of the car that are aluminum and there are a large number of smaller parts made of this light metal and its alloys."

Jigs and the Purposes They Serve.

Not everybody who has to do with automobiles fully understands the meaning of the word "jig" and the exact uses of that device, notwithstanding the very frequent use of the term when the subject of automobile construction is discussed.

Briefly stated, a jig is a fixture, usually made of cast-iron or steel, or both, which is attached to a machine to hold a part in the proper position for drilling, usually where more than one hole is to be drilled. For instance, if a jig were not used it would be necessary on every piece drilled to "lay out" the piece with scale, scratch awl and compass to determine where the holes were to be made. A jig made to exact dimensions is intended primarily to insure accuracy, perfect interchangeability, and of course save time and money in production.

In the Franklin cylinder base flanges, for instance, four holes are drilled, and their positions must be accurate within five-one-thousandths of an inch in order to "line up" with the other parts. To lay out and drill one of these flanges by hand would require at least an hour and a half of the time of an expert workman where with a jig the job can be done in fifteen minutes at the outside by any workman who can run a drill, and absolute accuracy is assured.

In mechanics other forms of jigs are recognized, but the drilling jig as probably the most common and the form most employed in automobile construction. When the large number of small parts used in an automobile are considered, it will be readily seen that the jig system is a most important item in producing a mechanically perfect car at a minimum cost to the purchaser.

Repairman Makes Frank Admissions.

"Have you ever found a satisfactory repair shop?" asks James Keenan, who is in the repair business in San Francisco, and who then answers his own query in this wise:

"No? Well, the chances are that you won't. Do you know that one of the expensive items for automobile manufacturing is that for 'testing' the completed car—finding what bolts have a tendency to work loose, what bearings run hot, what things squeak, work hard and fail to behave as they should, etc.—and every time your car is torn apart for repairs, it should have the same 'testing' as if it was just being built for the first time? Don't expect your car to come out of the shop in perfect shape, for it won't. Things are going to shake loose and run warm, just as they did when the car was new. The moral of this tale is, get a car that needs least repairs, that needs least dismantling to get at the principal parts."

NEWARK OBJECTS TO CONFETTI

And Arrest of Confetti-Thrower Disturbs Four States Tour—Otherwise Indiana "Boosters" Boost in Peace.

Not an incident worthy of the name disturbed the trail of Indiana automobile "boosting" talk which, in combination with much confetti, very much advertising matter and a considerable supply of music, both instrumental and vocal, marked that part of the Four States tour which lies between Akron and Canton, which was the night control reached Sunday last, 14th inst. Incidentless, also, was the trail from Canton to Wheeling, W. Va., which was reached on the evening of the 15th, and from Wheeling again across the state line into Ohio as far as Zanesville, the night control reached Tuesday evening, 16th.

The minds of the tourists were, for the time at least, taken from the exploitation of their respective vehicles when Newark was reached on the way from Zanesville to Columbus, for the first of the cars arrived just in time to see the official path marker, W. D. Edenburn, "pinched" by the local force, which impressed the Nyberg truck for use as a police patrol. At the station houes Edenburn was charged with littering the streets with confetti, which he distributed from the Great Western car so the course might easily be followed. The magistrate discharged the guide with a reprimand, and the tourists were warned not to distribute advertising literature within the city limits. Columbus was reached on the afternoon of the 17th, after an uneventful trip from Newark. The better part of the evening was spent at the banquet board, the host being the Columbus Automobile Club.

The run from Columbus to Chillicothe was hard and occupied most of the afternoon of the 18th. From Chillicothe the tourists proceeded to Portsmouth, but owing to the road building operations numerous detours were made necessary. At Portsmouth the tourists entered an automobile parade, which formed one number on the program of a local carnival. From Portsmouth the cars proceeded to Ironton, Ohio, from whence they were ferried across the Ohio river to Huntington, W. Va., the night control. Huntington was "wide open" to the "boosters," as, indeed, were most of the towns along the line of travel. Sunday, 21st, was the second and a very much needed "day of rest," and but few of the pilots stirred from the hotel.

Early Monday morning, however, even the sleepiest of the travelers was astir when the cars were loaded onto the steamer Castilia. The lines were cast off at 3 A. M. and the party enjoyed a 50-mile sail on the swollen Ohio to Maysville, Ky. Arrived, the Great Western pathfinder proceeded to mark the 63-mile course to Lexington, which was reached by the tourists on the afternoon of the 22d. From Lexington the course led over a tortuous, though a good, road to Louisville, where the party spent the evening of the 23d.

The Four-Staters are due to finish to-day in Indianapolis, from which city they "set sail" on July 9th.

AT LIMA, O.—ONE OF THE PEREMPTORY ORDERS THAT BID THE FOUR-STATE TOURISTS TARRY

At a meeting which resulted in the formation of the Edwardsville (Ill.) Motor Club, the following officers were elected: President, C. F. Rock; vice-president, L. D. Lawnin; secretary, Dr. E. H. Schwartz; treasurer, J. F. Ammann.

NO AWARDS IN WISCONSIN MEET

Too Many Perfect Scores Render Award of Trophies Impossible—Easy Rules and Good Roads Responsible.

Clean scores were the rule with the contenders in the third annual reliability tour of the Wisconsin State Automobile Association, which finished in Milwaukee, Friday last, 20th inst. For of the 14 participants in the event, 12 who were contesting for the Sentinel trophy and two for the Schandein cup—the latter for private owners—all but two finished without a demerit. As the contest finished with tied scores, both cups will remain in the possession of the association for the remainder of the year. The non-award of the trophies must be laid at the doors both of the contest committee of the promoting organization, which so modified the rules under which the cups were contested for, that penalizations were meted out only to those contenders who did actual work on the motors while on the road, and of the good roads enthusiasts along the line, who had put the roads traversed during the five days in such fine shape that the tour became a veritable "joy ride."

Monday, July 15th, was spent in the trip from Milwaukee to Beloit, the night control, 122 miles being covered. Roads were fine all the way, and but few of the contenders were delayed even by tire trouble. At Beloit the tourists were the guests of the Warner Instrument Co. at a banquet. Quite a few long stretches of sandy road were encountered on the second day's run to Baraboo—133 miles—but no machine was stopped on the road for repairs other

Digitized by Google

than to tires. Thirty-nine points were chalked against H. M. Heinemann, who drove the King entry, when on the third day's run from Baraboo to Oshkosh the water manifold developed an obstinate leak, which necessitated immediate repair. The other contenders, however, came through the 134-mile trip unscathed. W. S. Soules, who piloted the Flanders car, withdrew before the next day's journey—109 miles, from Oshkosh to Green Bay—was completed. A frozen piston induced by inadequate cooling and due primarily to a leaking radiator caused Soules to abandon hope of finishing. The other contenders reached Green Bay Thursday evening without mishap. The last 129-mile leg of the journey was finished on Friday. The score:

For Sentinel Trophy.

Emile Hokanson, Buick	Perfect
Jacob Hanson, Case,	Perfect
James Holmes, Krit,	Perfect
Jay E. Morehouse, Hupmobile	Perfect
W. H. Diener, Ford,	Perfect
Thomas R. Bell, Flanders,	Perfect
Charles Spooner, Oakland,	Perfect
R. D. Rockstead, Paige,	Perfect
H. R. Gallun, Marion,	Perfect
R. G. Bates, White,	Perfect
H. M. Heinemann, King,	39
W. H. Soules, Flanders,	Withdrew

For Schandein Trophy.

H. O. Stenzel, White,	Perfect
J. D. Babcock, Franklin,	Perfect

Frank M. Joyce Crosses "Great Divide."

After an illness of more than month, Col. Frank M. Joyce, first vice-president of the American Automobile Association, died at his home in Minneapolis on Monday last, 22d inst. He was 51 years of age. Colonel Joyce long had been one of the most prominent and influential figures in automobile affairs in the Northwest and played a conspicuous part in whatever he entered into. He had served as president of the Minneapolis Automobile Club and of the Michigan State Automobile Association, and but for certain untoward events would have been elected president of the A. A. A. at its annual meeting in New York in January last. He was in line for the presidency next year, and had he lived there is small doubt that he would have been chosen to fill the post.

Paris Reduces Its License Fees.

Resident motorists of that Paris which is in France have occasion to rejoice, for at the last meeting of the Municipal Council it was decided to make material reductions in license fees. The license on two-seated vehicles will be reduced from 50 francs ($10) to 31 francs ($6.20), and on vehicles having more than two seats from 90 francs ($18) to 55 francs ($11). These fees are in addition to the horsepower tax, which also has been proportionately reduced on vehicles of less than 37 horsepower.

DUST SHORTENS A MOROSS MEET

So Much of it at Wilkes-Barre that Safety Required Alteration of Program—Kyle Wins Four Events.

Dust, more dust, and then some more dust, necessitated the shortening of the program which was offered on Saturday last, 20th inst., at the Driving Park track, Wilkes-Barre, Pa., by E. A. Moross and his following. Not only were one or two events eliminated, but after the track conditions were ascertained by the running of the first heat for the Remy Brassard and trophy, the A. A. A. representative, T. B. Schoemacher, refused to allow more than two cars on the track at a time. Hence, even the heats for the Remy Brassard assumed a match race aspect and, owing to the fact that the track was but half a mile circuit, which permitted the cars to start on the second lap before the clouds of dust stirred upon on the previous lap had had time to settle, all three were cut to two miles.

The advertised 25-mile race for cars with displacements under 600 inches became a two-mile match race between Burman (Cutting) and Kyle (White), and was won by the latter in 2:55. The first heat for the Remy Brassard went to E. A. McDonald, who finished the two miles in the Benz in 2:45, leading home Burman (Cutting). Hickman (Mercedes) and Kyle (White) dropped out after the first lap on account of the dust. The last two heats which were contested between Burman and McDonald went to the former in 2:42⅕ and 2:47, respectively. Burman drove an exhibition mile in 1:12 at the wheel of the Blitzen Benz. Driving the Cutting, he came off second best in a match race with Kyle (White), who finished the five miles in 7:43⅗. A second match race, which, however, went for only two miles, also resulted in a victory for the White pilot, who finished in 2:42⅕. In the time trials, Kyle (White) and McDonald (Benz. completed a single mile in 1:19⅕, while Burman (Benz) set the time at 1:15⅗. The summary:

Five miles, match race—Won by Kyle (White); second, Burman (Cutting). Time, 7:43⅗.

Two miles, for the Remy Brassard and trophy. First heat—Won by McDonald (Benz); second, Burman (Cutting). Time, 2:45. Second heat—Won by Burman (Cutting); second, McDonald (Benz). Time, 2:42⅕. Third heat—Won by Burman (Cutting); second, McDonald (Benz). Time, 2:47.

One mile, time trial—Burman (Benz). Time, 1:12.

Two miles, match race—Won by Kyle (White); second, Burman (Cutting). Time, 2:42⅕.

Two miles, match race—Won by Kyle (White); second, Burman (Cutting). Time, 2:55.

Sued, Claims he Played Good Samaritan.

Charles J. Petbury, of Brooklyn, N. Y., has ceased to take stock in the Good Samaritan story, and, if his tale be true, not without good reason. Petbury has been made defendant in a suit brought by Mrs. Mary Holland, as administratrix of the estate of her husband, Michael Holland, who, she claims, was knocked down and killed by an automobile driven by Petbury on May 2nd last. Petbury's answer is almost more than a plea of not guilty. He declares that, instead of knocking down Holland, he succored him. He alleges that the deceased had been knocked down and run over by a runaway horse, and that while he was lying injured on the road he (Petbury) happened along in his automobile and ran over the prostrate man. Petbury asserts that instead of being responsible for the death of Holland he is more deserving of thanks, as he picked him up and rushed him to a hospital, thereby acting the part of a Good Samaritan. Mrs. Holland, nevertheless, asks for $10,000.

Electric Car Chosen A. A .A. Pathfinder.

For the first time in the history of what is termed pathfinding, an electric vehicle—a Flanders—will undertake to lay out the route of the A. A. A. national reliability tour from Detroit to New Orleans, that privilege having been awarded to the Flanders Mfg. Co., of Pontiac, Mich. The car, which will be directed by W. O. Westgard, an A. A. A. road expert, is to start from Detroit on Monday next, 29th inst., and, though the 1,100 miles route is strenuous and paved roads are few and far between, it is expected that the undertaking will be completed within two weeks. As charging stations are even fewer and further between than macadam roads, special arrangements are being made for recharging along the line. It is officially stated, however, that the details of the route will not be made known until the return of the pathfinder.

Seeking to Make St. Johnsville Disgorge.

Andrew Carnegie has not yet bestowed a library on the good people of St. Johnsville, N. Y., but whether it was for the purpose of erecting a structure just to make the philanthropist feel cheap, or whether some equally worthy motive prompted the town authorities to "pocket" the fines collected from automobile speeders, as charged by the New York Automobile Association, doubtless will be explained in court. Members of clubs affiliated with the State Association complained of fines imposed by the St. Johnsville authorities and an investigation revealed that the fines collected were not forwarded to the state treasury as required by the motor vehicle law. Proceedings to recover $5,000 are to be instituted by the association.

Digitized by Google

1,012,247. Spare Tire Cover. Hyman Cohen, New York, N. Y. Filed Dec. 7, 1908. Serial No. 466,215.

1. A tire cover, comprising a casing provided with overlapping flaps at its opening, and a flat resilient core in the outermost flap for forcing the same against the inner tire face, said core comprising a plurality of sections foldable upon each other.

1,012,288. Explosive Engine. William Stephenson, Newport, Ky., assignor to The Fox Reversible Gasoline Engine Company, Newport, Ky., a Corporation of Kentucky. Filed Sept. 30, 1909. Serial No. 520,367.

1. In an explosive engine, a compression and combustion chamber, a piston and crank shaft, an inlet for the mixed charge into the compression chamber so located as to be uncovered by the piston at the end of the suction stroke, an independent conduit between said chambers, an air inlet in said conduit for admitting air into the compression chamber on the suction stroke of the piston, and an exhaust port leading from said combustion chamber.

1,012,325. Tire Protector. John O. Caldwell, Jr., Boston, Mass., assignor of one-half to John O. Caldwell, Sr., Boston, Mass. Filed Mar. 19, 1910. Serial No. 550,446.

1. A tire protector comprising two relatively stiff members curved on radii corresponding respectively to the inner and outer curved surfaces of a tire shoe, and a flexible web connecting one edge of each member, the free edge of each member being provided with a flexible flap.

1,012,353. Tire Protector. Joseph C. Hammer, Chicago, Ill. Filed Nov. 7, 1910. Serial No. 591,053.

A tire protector comprising companion arms, said arms swinging around a common pivotal center, a shield-like member on the outer end of each of said arms oppositely disposed to one another and clamping the tire on opposite sides thereof, said arms being free with respect to the wheel body, whereby the shield-like members may be adjusted to the desired position upon the tire body, tension mechanism for holding the shield-like members in engagement with the tire body comprising a tension member located at one side of said pivotal center and exerting force tending to throw the shield-like members into engaging position with the tire, a boot positioned on said tire, and means for locking said boot to said shield-like members, substantially as described.

1,012,356. Asbestos Brake Band. Louis R. Hoff, Paterson, N. J., assignor, by mesne assignments, to The Asbestos Brake Company, a Corporation of New Jersey. Filed Nov. 5, 1909. Serial No. 526,432.

1. A brake provided with a liner comprising a layer of asbestos fabric impregnated with a drying oil and having a wire reinforcement.

1,012,367. Detachable Wheel Rim. Karl Kindscherf, Hanover, Germany, assignor to Continental-Caoutchouc & Gutta-Percha-Compagnie, Hanover, Germany. Filed Nov. 10, 1910. Serial No. 591,625.

1. In a detachable wheel rim, an engaging claw pivoted to the detachable rim, a flange rigid with said rim and a friction device carried by said claw and bearing against said flange to hold said claw in the position to which it may be adjusted on its pivot.

1,012,374. Spring Wheel. Emil M. Larson, Canby, Minn. Filed May 16, 1911. Serial No. 627,601.

1. A wheel, comprising a hub, a rim, a plurality of spokes connecting the hub and rim, a sectional tread surrounding said rim and spaced therefrom, said tread being composed of a plurality of tread members the ends of which are hingedly secured together by pintle bolts, a plurality of auxiliary spokes slidably mounted in said hub, the outer ends of said auxiliary spokes terminating in yokes which straddle said rim, the free end of said yokes being secured to the tread by means of the pintle bolts of the hinges thereof, a plurality of U-shaped clips secured to the rim and engaging said yokes to maintain the same in proper position with respect to the spokes while at the same time permitting radial motion of the auxiliary spokes, and cushioning means between said auxiliary spokes and the hub.

1,012,375. Tire. Frederick H. Lathrop, Chicago, Ill. Filed May 17, 1911. Serial No. 627,719.

A vehicle tire comprising a rim provided with annular flanges and provided with apertures, blocks provided with a groove and with apertures, and provided with an overhanging lip on one side thereof, said blocks arranged to fit on the rim and to extend through the apertures in the rim, a rubber band arranged to fit the rim, a cover consisting of metal pieces provided with bends adjacent to their ends, and extending transversely across the rubber bands, and wires over the ends of the metal pieces, and means to secure the ends of the wires in the blocks, said blocks arranged so that the overhanging lips thereon cover the ends of the metal pieces which abut against said blocks.

1,012,380. Mixer for Internal Combustion Engines. Robert D. Loose, Chicago, Ill. Filed Feb. 7, 1910. Serial No. 542,503.

1. A mixer for internal combustion engines, comprising, in combination, a casing, means at the top and the bottom of said casing whereby said casing is adapted for connection to the intake pipe of such engine, a regulating valve in said casing, a series of conduits in said casing occupying the entire interior space in said casing and affording a series of straight and unobstructed passages in said casing through said conduits and through the interstices between said conduits, said conduits having in their walls minute spaces adapted to retain moisture by capillary attraction, said conduits presenting to the ascending explosive mixture the narrow edges only, and means above and below said conduits to retain them in said casing.

1,012,408. Change Speed Mechanism. Robert Milne, Rockford, Ill. Filed June 29, 1911. Serial No. 636,039.

1. In a change speed mechanism, the combination of a drive shaft, a driven shaft, a supplemental shaft, a series of gears on the supplemental shaft positively locked thereto, a series of gears on the driven shaft opposed to the gears on the supplemental shaft, at least one series of gears being stepped, means for connecting the drive and driven shafts together, a gear connection between the drive and supplemental shafts, including a shiftable gear, means for disconnecting the drive and driven shafts when the gear connection between the drive and supplemental shafts is made, a shiftable gear for each set of opposed gears of the series of gears.

1,012,459. Vehicle Tire. Albert L. Siegrist, Akron, Ohio. Fied Oct. 10, 1910. Serial No. 586,161.

A vehicle tire comprising a rim formed of a plurality of sections, each section consisting of a member having inwardly extending side flanges adapted to embrace the felly and outwardly extending hook portions projecting in a direction opposite to said flanges, means for securing each section to the felly and a block of resilient material permanently secured between said hook portions.

1,012,562. Steering Gear for Automobiles. Charles B. King, Detroit, Mich., assignor of one-half to Ora J. Mulford, Detroit, Mich. Filed July 21, 1910. Serial No. 572,956.

1. In an automobile, the combination of an axle, an approximately vertical bearing thereon, an arbor in said bearing, a stub-axle extending laterally from said arbor above said bearing, a laterally extending lug on said bearing, and a lug extending from said arbor above said bearing over and under the lug on said bearing.

1,012,658. Hood Fastener for Automobiles. Carl C. Kusterer, Grand, Rapids, Mich., assignor to Keeler Brass Co., Grand Rapids, Mich., a Corporation of Michigan. Filed Apr. 15, 1911. Serial No. 621,350.

1. A fastener, comprising a spring case, a shank adjustable in the case, means for pivotally attaching the shank, a spring in the case, a rod engaged by the spring and projecting outside the case, and means for detachably securing the projecting end of the rod.

1,012,670. Windshield for Motor Vehicles. Allen Loomis, Detroit, Mich., assignor, by mesne assignments, to Packard Motor Car Company, Detroit, Mich., a Corporation of Michigan. Filed Oct. 15, 1907. Serial No. 397,573.

1. A windshield arranged for connection to vehicles comprising a lower panel hinged to suitable supporting means and adapted to swing forwardly, an upper panel hinged to the top of the lower panel and adapted to swing backwardly with reference to the lower panel, guide rods at the ends of the panels, and means for adjustably securing said panels to the rods.

1,012,730. High Tension Magneto Electric Machine. Frederick Richard Simms, London, England, assignor to The Simms Magneto Company, a Corporation of New York. Filed Feb. 23, 1910. Serial No. 545,453.

1. In a high tension magneto electric machine, the combination with the armature provided with separated lateral cheeks, and end plates connected therewith, said cheeks being extended at one end beyond the armature coil, to form a housing, of a condenser fitted tightly between said cheeks within said housing and a ring surrounding said cheek extensions and condenser, said condenser being held by said ring and cheek extensions from movement and vibration with respect to the armature during the rotation of the same.

1,012,796. Vehicle Wheel. John N. Bartle, Wichita Falls, Tex. Filed Oct. 28, 1910. Serial No. 589,639.

1. In a wheel, a rim, a hub, and spokes

Digitized by Google

carried by the hub, the rim being formed with spaced flanges, and the curved spring spokes seating at their outer ends between the flanges and frictionally engaging the rim between the flanges and forming a pawl and ratchet connecting means therebetween.

1,012,828. Storage Battery. Thomas A. Edison, Llewellyn Park, West Orange, N. J., assignor to Edison Storage Battery Company, West Orange, N. J., a Corporation of New Jersey. Filed May 24, 1910. Serial No. 563,842.

1. In a storage battery, the combination of a row of tubular electrodes of one polarity, a row of flat electrodes of opposite polarity parallel to said tubular electrodes, and non-conducting separators each arranged to contact on one of said flat electrodes and two adjacent tubular electrodes to prevent contact between said flat electrodes and tubular electrodes, said separators being arranged to have substantially point contact only with said tubular electrodes, substantially as described.

1,012,847. Motor Driven Steering Axle for Motor Vehicles. Charles B. Hatfield and Charles B. Hatfield, Jr., Cornwall-on-the-Hudson, N. Y. Filed Mar. 20, 1910. Serial No. 552,129.

1. In a motor vehicle, the combination with an axle having a pivotal connection with the frame for steering, of a ball member secured to the axle, a driven gear surrounding the axle, a spherical ring mounted and snugly fitting on the ball member and having a convex surface upon which the gear is mounted, and pivotal connections between the ring and the ball member and between the ring and the gear at substantially right angles to each other.

A trouble saver for the motorcyclists

This book contains more practical advice for the rider, more good hard sense, more suggestions as to how to keep out of trouble, and how to get out of it, than has ever been printed heretofore in any one book.

¶ It fits the coat pocket and it includes free engine clutches, two-speed gears, mechanical lubricators and magnetos, together with special matter on motors, valves, carbureters, fuel and important general subjects, all plentifully illustrated.

¶ Dealers and jobbers in all parts of the country are selling "Care and Repair of Motorcycles" to both new riders and veterans as the best aid in correcting and avoiding motorcycle trouble.

Weed Chains

The Great Anti-Skid DEVICE

Nine-tenths of all accidents to automobiles are caused by skidding or slipping.

Either you skid into the "other fellow" or the "other fellow" skids into you.

No matter how careful a driver you may be, you cannot prevent skidding or slipping on wet, muddy snow-covered roads or on icy, slippery greasy pavements unless you equip your car with Weed Chains.

Cannot Injure Tires

Because They Creep

An absolute necessity on both rear wheels and if you want to know what real steering steadiness means put them on the front wheels too.

For your own safety—for the safety of the public, fully equip your car with Weed Chains. Make it your business to get a set today.

Here is an accessory that does away with the terrors of cold during winter driving.

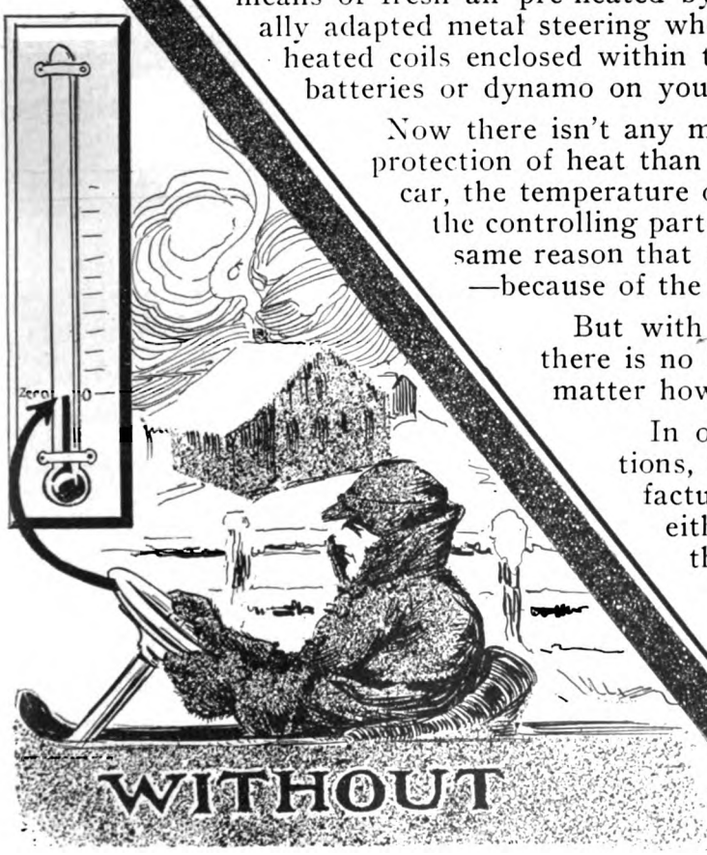
The Warm Hand Wheel will keep your hands and feet just as warm in zero weather as they would be if you were driving this minute.

The Warm Hand Wheel not only makes winter driving comfortable but it eliminates the danger of accidents due to cold, benumbed hands—also, hands heavily bundled up to keep out the cold.

WITH

We can supply you, or your customers, with the Warm Hand Wheel. Be a "progressive"—don't "stand pat" and handle a car that is so far behind the times as not to be equipped to warm the person who is driving it.

WARM HAND WHEEL



Insist upon heated steering wheels for winter driving. Not only do they mean safety and comfort—but they mean more cars sold in winter. If the manufacturer will not supply them write us and we will tell you how to get them on your cars.

The Warm Hand Wheel is a simple device which operates either by means of fresh air pre-heated by the motor and supplied to the specially adapted metal steering wheel; or, by means of a pair of electrically heated coils enclosed within the steering wheel and operated by the batteries or dynamo on your car.

Now there isn't any more sense in driving in winter without the protection of heat than there would be of riding in a Pullman palace car, the temperature of which was zero. The question of heating the controlling parts of an automobile has been neglected for the same reason that many other refinements have been neglected —because of the rapid growth of the industry itself.

But with the perfection of the Warm Hand Wheel, there is no longer any excuse for aught but comfort no matter how cold the weather may be.

In order to meet the requirements of all conditions, the Warm Hand Wheel is now being manufactured so as to be operated, as stated above, either by means of fresh air so circulated around the motor as to become thoroughly heated; or by using electricity—whichever system is best suited to the particular requirements of your car.

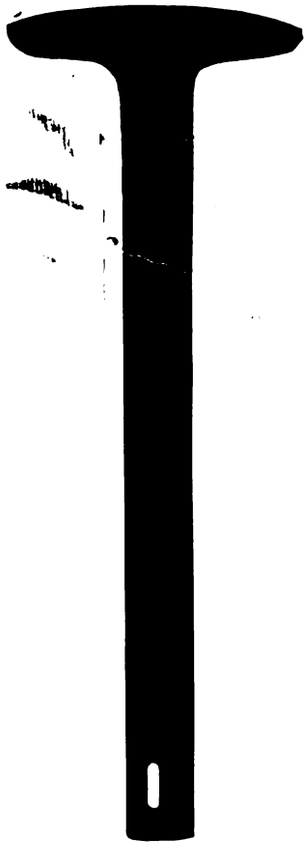
FEDERAL TIRES

Are Entitled to a Trial

FEDERAL Tires are now permanently used by many automobilists, because they have tried these tires on the strength of our claims of their superiority.

Federal Tires will demonstrate in every instance that they are worthy of their reputation as the tires of "Extra Service." They are more satisfactory and last longer than other tires. Try these unusual tires and note the economy.



Made in all types for all standard rims.

Federal Tires are supplied through leading dealers everywhere. An interesting tire book mailed to all who write.

Federal Rubber Manufacturing Co., Milwaukee

Branches and Agencies:— *New York, Boston, Chicago, Kansas City, Minneapolis, Denver, Indianapolis, Columbus, St. Louis, Louisville, Omaha, Houston, San Antonio, Little Rock, Atlanta, Los Angeles, San Diego, Pasadena, New Orleans, Portland.*

"Extra Service"

THINK THIS OVER

very carefully and read it twice, if necessary.

Is there any part of an automobile engine, or any other gas engine, that is more important to its efficiency than a Valve?

Your engine leaves the factory running smoothly and sweetly—tuned up to its highest power. Perhaps the valves pit—warp—go out of shape—fail to hold compression. Then the power diminishes, and what can be more aggravating to the driver, who has known the fullness of the pulling power of his motor, than to have it grow less and less?

You cannot slight this part by putting in an inferior product—valves that will give trouble, or even break from inexperience in their manufacture—valves of unsuitable material, not suitably heat treated.

Too much is at stake, and a slight extra cost at the outset, which is the exception, may save you many times over a probable later expense.

This Company, with the experience of many years as a guarantee, will furnish you with properly made valves, of the materials best adapted to your requirements.

Not only QUALITY, but efficient SERVICE is a factor—surely there is a satisfaction in getting the kind of work you want—when you want it.

Mr. Automobilist:

Your tire maker is very anxious to impress upon you the importance of

Tires Inflated to the Right Pressure

He insists that this is tire economy and

Saves You Money

How do you know what pressure you have in your tires? A

SCHRADER
UNIVERSAL
Tire Pressure Gauge

(Trade Mark Registered in U. S. Patent Office)

(Patented March, 1898—Other Patents Pending)

will tell the exact pressure in your tires at any time, day or night, by simply holding this Gauge to your Valve for a second. Its recording sleeve remains in place, showing the exact pressure in the tire so that the Gauge can be taken anywhere and read, at night to the front of the car into the light of the lamps. After the pressure has been ascertained the Indicating Sleeve can be pushed back into the Gauge with your finger. No catches or snaps to operate or get out of order. This Gauge is 2½ inches long over all, short enough to apply easily to the smallest diameter of wheel and can easily be carried in the vest pocket or the change pocket of your trousers.

4 Square Reasons Why You Should Choose the Glide

Our New Model 36-42 H. P.

Complete Equipment

$1550

The careful buyer, and the dealer who is alive to the real automobile situation are invited to write for handsome FREE book and learn from this book why the Glide is ***best.*** Booklet pictures and describes full line including Two and Four-Passenger, 45 H. P. Cars, $2,000; Five-Passenger "45," $2,150; Seven-Passenger "45," $2,250.

EFFICIENCY
For style, comfort, luxury, quality of construction, mechanical perfection—in all that goes toward a car's efficiency—the buyer of a "Glide" actually gets more automobile value than can be obtained from cars costing at least $1,000 more.

SERVICE
The "Glide" is not the only first-class car on the market, we admit that. But unlike other automobiles, the "Glide" is not merely a "one-year" car. We make the "Glide" for 5 to 7 years' continuous service. This we guarantee.

PRICE
While the "Glide" is not a high-priced car—remember it is not a cheap car. The standard of construction equals that of cars costing the highest price. Consequently the buyer gets a car second to none in quality at a cost that's as low as any standard make.

GUARANTEE
The purchaser of a "Glide" is protected by a guarantee more liberal and wider in scope than any other guarantee ever issued. Read it in the FREE book—sent on request. It will surprise you.

New Selling Agencies

are now being established in select territory. If interested, write us for our special proposition. "Glide" dealers can offer their trade a car that combines quality and service that at the price has never been equalled. Get this FREE book and full details.

INNER TIRE

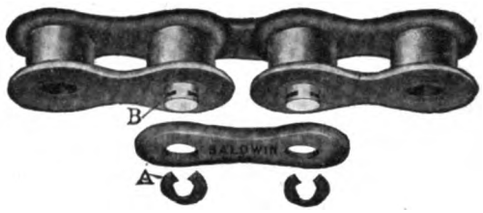
Interlock

INTER LOCKING FLAP

Inner Tire

¶ Don't confuse the Interlock Inner Tire with the multitudinous reliners and tire saving devices now on the market.

¶ Remember that the Interlock is a complete inside tire, quickly and easily inserted in the outer shoe and guaranteed to withstand the hardest kind of treatment without danger of blow-outs.



¶ The fabric used in the construction of the Interlock is 4, 5 or 6 ply, according to the size of the tire.

¶ With it blow-outs, rim-cuts, or punctures are practically impossible and as money savers they have made records that are almost unbelievable.

¶ Get the full details. We have some interesting literature which describes the Interlock Inner Tires in full.

¶ As a dealer it will pay you to know more about this tire saver—also about our liberal commission.

The New Twitchell Positive Lock Stop Gauge

There are many types of Gauges on the market, but do you really know of any that are accurate?

We Know Your Answer

Now listen to what we have to say about the NEW TWITCHELL POSITIVE LOCK STOP ACCURATE GAUGE:

1—Correct pressure is insured in all your tires.
2—Its construction is simple.
3—No rubber washers to wear out or deteriorate as in all other Gauges.
4—Absolutely no friction or wear on internal or external parts.
5—In testing this Gauge it passes through four different hands, the last test being inspection.

GET MILEAGE! Correct pressure, and pressure in all your tires are essential to your mileage.

The use of the new Twitchell Air Gauge enables you to attain this. IT IS ACCURATE, SIMPLE AND INSTANTANEOUS, made to carry in the vest pocket and is only 3½ inches long.

No better tire insurance could be produced than a LOCK STOP FEATURE TWITCHELL AIR GAUGE. It can be just as easily read at night as day—the graduated bar remains at the pressure indicated until a slight pressure of the thumb on the extreme end of the ratchet side returns the register to zero.

Correct Pressure for Tires:		
2½"	Tires.....	50 lbs.
3"	Tires.....	60 lbs.
3½"	Tires.....	70 lbs.
4"	Tires.....	80 lbs.
4½"	Tires.....	90 lbs.
5"	Tires.....	90 lbs.

THE TWITCHELL AIR GAUGE IS TIRE INSURANCE FOR ONE DOLLAR.

Can be Obtained from Your Dealer.

K·D
The Motor With the Sliding Crescent Valve
KNIGHT-DAVIDSON
1896 — 1912

The CRESCENT valve of the K-D Motor, fitting around the stationary piston wall affords a larger port area than any other poppet or slide valve on the market. It is simpler and, consequently, better than any other valve construction known and is here offered to discriminating manufacturers, not as an experiment, but as a tried, tested and proved mechanical advance. The K-D motor is simple, silent, cools rapidly, has the simplest oiling system known, will not carbonize. Last and most important, will give on a given quantity of fuel more power, speed and endurance, unit for unit, than any other engine on any type of an automobile. We want to present some facts to interested manufacturers.

The Motor Lamps with Distinctive Features

There are no other motor lamps on the market with the advantages of Solar Lamps. Solars are always exclusive in style and in quality. They are the strongest lamps as well as the most effective.

In no other lamps can you obtain the Solar Special Short Focus Lead Glass Lens Mirror Reflector—the patented system of double ray light projection which gives two distinct fields of light for town and country use—or the new and exclusive black finish with a metallic lustre which is unaffected by heat or moisture. All of these features are exclusively "Solar."

Do not equip your car or specify equipment to the maker until you have seen all of the Solar advantages. See Solars at any live dealer's or write for the catalog.

Solars are made in all styles for oil, electricity, gas and in combinations.

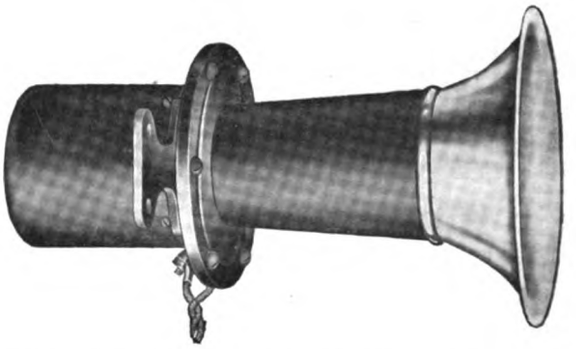
KLAXON

The Name of the New Signal is

KLAXET

THE AWARD OF $100 was made to H. I. Stengel, Esq., Spring Lake, N. J., for the name "Klaxet."



Several others submitted the same name, but the suggestion of Mr. Stengel was the first to be received.

"Klaxet" was chosen from the more than ten thousand other names submitted, for the following reasons:—

(1) It harmonizes consistently with "Klaxon" and "Klaxonet", and yet there is sufficient distinction to prevent confusion: The difference in appearance of "et" and "on" removes it from "Klaxon", its shortness from "Klaxonet".

(2) The source of the word "Klaxet" is at once apparent. It immediately brings to mind "Klaxon", and says without further explanation that the signal is made by the same makers. This point is valuable, because the word "Klaxon" is universally known. It is synonymous in the minds of the public generally with "automobile horn." "Klaxon" is the most valuable single trademark in the accessory field.

(3) "Klaxet" is short, easily remembered, easily handled in type.

MOTOR DRIVEN $12

COMPLETE WITH WIRE AND PUSH-BUTTON

THE name has been chosen. From August 15th orders will be accepted—and filled in the order of their receipt. Deliveries will begin on the first of September.

The advent of the Klaxet means the *certain elimination* of the bulb-horn!

It means a swift "revision" in the prices of signals of *other* types.

The Klaxet—perfectly made, fully guaranteed, invariably reliable—loud, abrupt, a *real warning*—economically operated; an *adequate* MOTOR-DRIVEN signal at TWELVE DOLLARS—will establish a new standard of signal values!

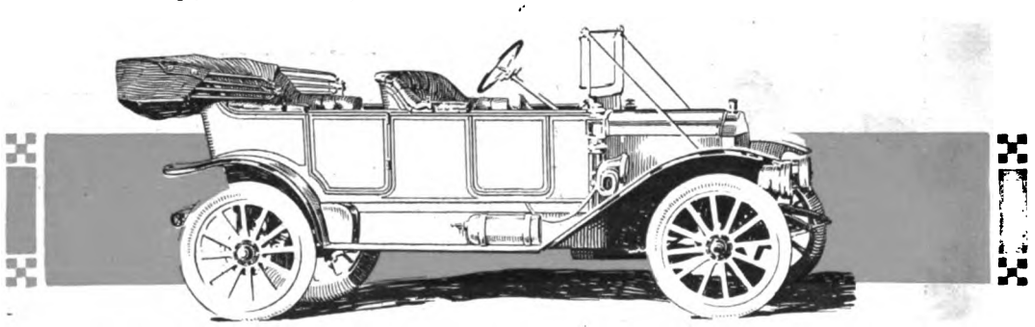
Studebaker

The All Important Question of Repair Parts

Convenience in getting repair parts—their cost when he does get them—are serious questions to every car owner. These considerations alone make the "assembled" car a dangerous experiment.



When he needs a new part, the owner of an "assembled" car has to wait for it—for days at least, perhaps weeks, perhaps months, and in addition to the annoyance and loss of time, face an expense bill out of all proportion to the actual value of the part.

Studebaker car owners have none of these troubles. Every car part is made in the Studebaker factories—made with automatic machinery which ensures absolute uniformity and precision and reduces cost to a minimum.

Change for the sake of novelty, moreover, has never been a Studebaker policy—and experience shows, that we have left little to improve and few mistakes to correct. Studebaker parts consequently do not vary and do not have to be made up specially from discarded patterns. With 36 Supply departments and 2000 equipped dealers over the country any part can be replaced at a moment's notice at very slight cost.

The quality of Studebaker parts, also, reduces the percentage of breakage to the lowest possible point. All material is tested for quality in our own laboratories and every part tested for strength at every step in its manufacture.

These are some of the facts that account for the clean, unrivaled record of Studebaker cars and their immense selling strength among dealers and owners.

The $800 Studebaker (Flanders) "20"

NON SKID
TRADE MARK

ANNOUNCEMENT

IT IS our policy to promote the sale of Pennsylvania Tires both by maintaining the highest possible standard of quality and by devotion to the Dealer's interests, in order that he may be assured of a fair profit for service rendered in distributing our products.

Our remarkable guarantees, and the fact that the tires have more than fulfilled those guarantees, have created such an enormous demand that we are now enabled to offer the trade the most attractive proposition we have ever made on

PENNSYLVANIA VACUUM CUP TIRES

Our extensive advertising has created a growing interest among motorists who had not been familiar with these tires, but who are now ready buyers.

As we distribute only through the highest-grade Dealers, there is an opportunity for many to secure practically a monopoly in the sale of Vacuum Cup Tires in districts in which we are not now represented.

To each tire is attached an envelope containing the definite printed guarantee of 4,000 miles actual service.

Purchase price refunded if a car equipped with Vacuum Cup Tires skids on wet or greasy pavements.

Write at once or call at nearest branch.

The grinding department of this plant is what may be well termed "different and better" for we have designed and built many of our own grinding machines to meet special and hard requirements, which could not be met on the ordinary run of grinders.

Every process involved in the making of universals and cone clutches conforms with unyielding precision and every part of every universal and cone clutch has a limit of tolerance far beyond the point that could be reached in actual working conditions.

It costs good money to produce parts that are stressed to the "Hartford" standard—but this works out for us as a reputation builder and for you, Mr. Car Manufacturer, as an assurance of quality that will do its part in establishing and holding your reputation.

Now, back of these claims, we can show you prices on quantity production that will make you wonder just how we do it.

We stand ready to tell investigative engineers just how experience, plus facilities, can produce cone clutches and universal joints good enough to make good cars still better.

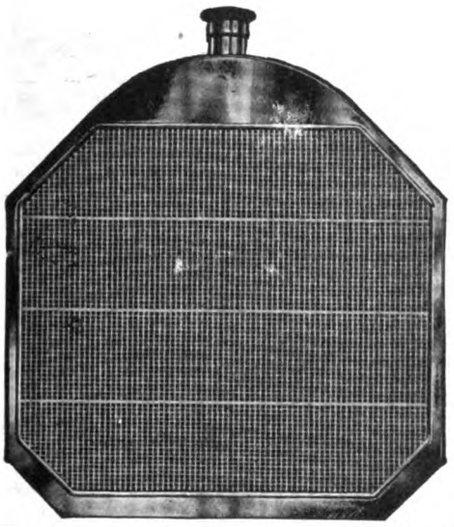
EXPERIENCE — SHELDON — RIGHT DESIGN
FACILITIES — AXLES — RIGHT STEEL
"Made in the Largest Axle Factory in the World"

Axle Talk—No. XIII

SHELDON practice is exact.

SHELDON organization is just an assembly of scientific and engineering methods that must, of necessity, automatically throw out, reject and "scrap" any part of any axle that can't conform to SHELDON standard.



A physical laboratory, a chemical laboratory, an engineering staff composed of men who have made springs and axles a life study—modern instruments of research, consisting of testing machinery for materials, endurance machines to study the life of that which formerly was considered inert matter—chemical laboratories which study the biology and the pedigree of materials—machines for studying the strength of their products under static and dynamic forces. These, and many other appliances too numerous to mention, have replaced and added to their hold of new methods of production.

If SHELDON methods of getting only the best out of materials and construction appeal to any engineer who has been up against it in this particular, then he's the man we want to talk to.

The M & P Electric

PRICES:

Chassis
$1450

Express Body
$1500

Enclosed Body
$1600

THERE is no doubt but that thousands of concerns prefer the electric truck to the gasoline type, but up until this time they have been balked through the prohibitive prices charged for the electric truck.

We do not have to tell the dealer, nor the prospective buyer, that until the M & P Truck was placed upon the market, $2200 was about the lowest price for which a truck of this description could be bought.

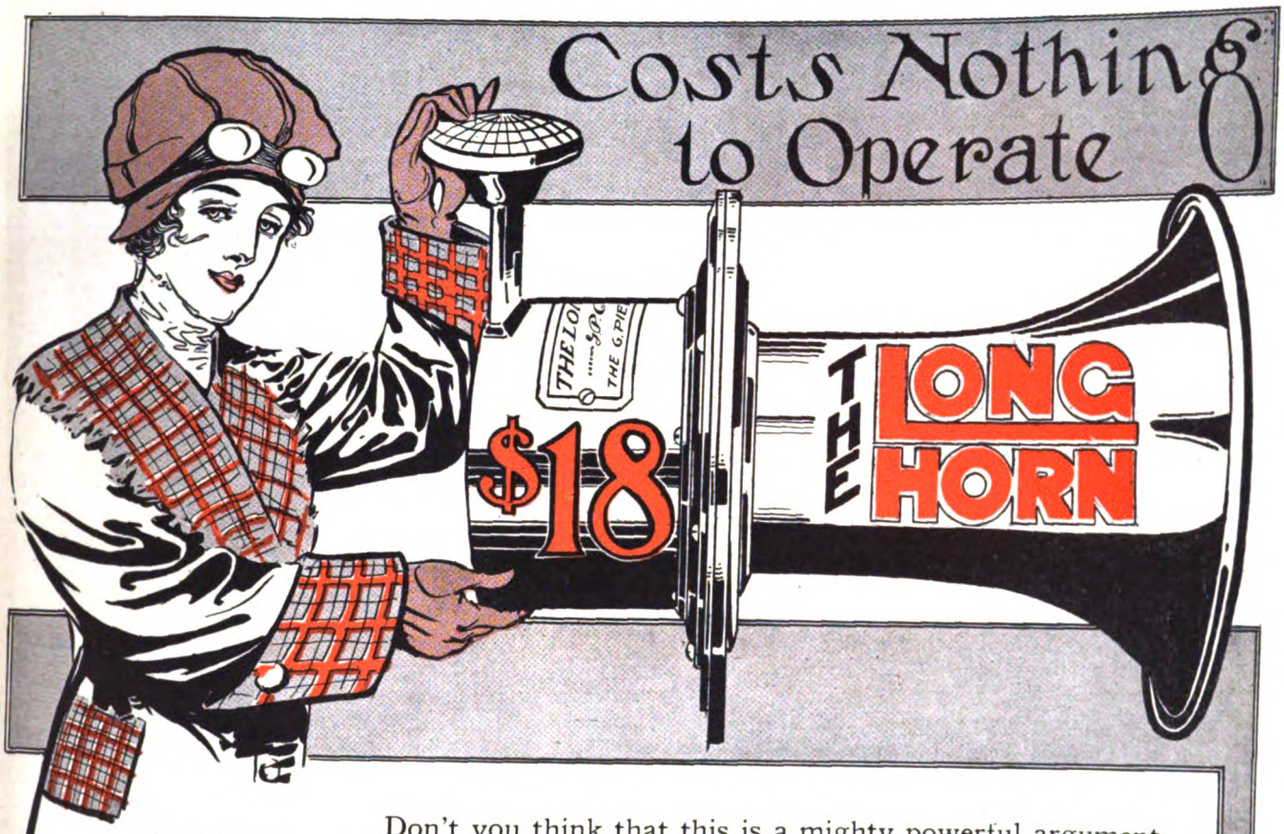
We offer here now to your trade, Mr. Dealer, a high-grade, sturdily built, dependable electric truck with express body, as shown here, complete for $1500.

Do not presuppose that this price indicates inferiority. Remember we guarantee the M & P Truck to perform more and better service at a more moderate cost than could a gasoline truck selling for much more.

Electricity is the logical motive power for the handling of merchandise. This has been proved and over-proved.

And so it is that truck owners and prospective truck owners will welcome this announcement, because it puts a standard, dependable car within the reach of the average business concern that needs it.

The proposition we have to advance to dealers is very attractive. Primarily, of course, price is a big consideration, but when we tell you more about the quality, simplicity and grace of this truck, you will be interested.



You will be still more interested in learning of the liberal commission and easy terms we make to responsible dealers. It will pay you to get this information.

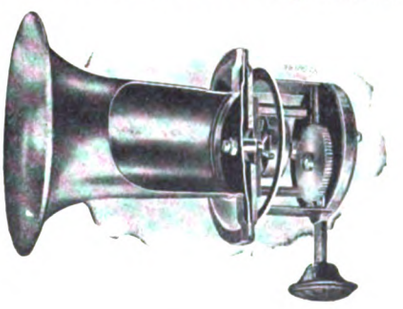
Costs Nothing to Operate



Don't you think that this is a mighty powerful argument for the sale of a warning signal—the fact that it "costs nothing to operate"?

As a matter of fact, this is the least important point to be considered in the sale of the Long Horn. The most important feature is that the Long Horn can never fail to operate. If the driver of the car can push the button the horn will always sound its warning note.

It is this fact—the never-failing feature—that makes the Long Horn stand out pre-eminent among all warning devices. The Long Horn is not an electric horn. It is the superior of any electric horn even when that electric horn is working. The Long Horn is a mechanically operated horn, free from motors, batteries, bulbs and wires. There isn't an accessory on the market that sells so well as the Long Horn. There is a big margin of profit in it for the dealers and it's a mighty fine asset to have on your shelf. Don't wait—get in touch today.

Just as Warm in January as in August

TO ALL intents and purposes driving in January is just as comfortable as driving in August, provided the car you operate is equipped with a Warm Hand Wheel.

This Warm Hand Wheel, by using fresh air preheated by your motor, or by using a special electrical attachment, which takes the place of hot air, will keep your feet and hands just as warm in January as they are in August, or warmer if you desire.

It is a fact that if your hands and feet are warm your whole body is warm, so that the Warm Hand Wheel will absolutely make driving on the coldest day in winter thoroughly warm and comfortable without the use of burdensome clothing and wearing apparel.

The Warm Hand Wheel makes winter driving safe by preventing cold, benumbed hands. The Warm Hand Wheel saves doctor bills by preventing you from becoming chilly and catching cold during winter driving. The Warm Hand Wheel enables you to get more days driving out of your car than you would without using it.

DEALERS — This Accessory Means Greatly Increased Car Sales for You.

You know that if as many people drove cars in the winter time as in the summer time, that you would sell a lot more cars and that the supply and accessory business would be much more brisk.

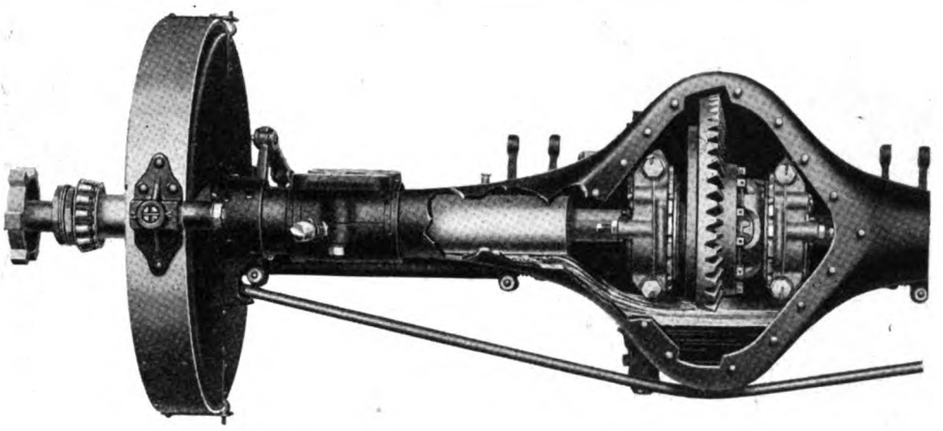
You know also that if people could keep as warm and comfortable in winter as they do in summer there would be a lot more people driving in winter.

Then it is up to you to boost for the Warm Hand Wheel.

Why?

Because the Warm Hand Wheel makes winter driving just as comfortable as summer driving.

We are in a position to supply you or your customers with the Warm Hand Wheel—either the type using hot air or the one which operates by electricity.



Insist that the cars you handle next year be provided with heated steering wheel—not alone because you will sell more cars, but because it will mean safety and comfort for your customers.

If your manufacturer will not supply you these steering wheels, get into communication with us and we will tell you how to get them.

Warm Hand Steering Wheel Co.
527 Fifth Avenue **NEW YORK**

There's Danger to Life in Oil-Soaked Brake Linings

Sometimes—to avoid a crash—you have to jam on the brakes and stop your car mighty quick.

It may mean life or at least a bad smash if those brakes don't grip safe and sure. Oil-soaked brake linings are dangerous at such a time.

TIMKEN-DETROIT AXLES

have pockets to retain the oil

Time was, with all axles, when oil from the differential used to work along the live axles, leak out at hubs and get into the brake linings.

Time was, when it stained the wheels, ran down the spokes and injured the tires.

Just as it's doing today in many good axles.

But the new internal sleeve in the 1912 Timken-Detroit axle-housing has put a stop to that trouble.

All the oil now stays at the differential where it belongs.

So simple it's a wonder we didn't think of it long ago

Really effective things are almost always simple. Yet often they're found only after trying all the complex ways one can work out.

We put reinforcing sleeves in the Timken pressed steel housing to increase its ability to carry the load.

The outer ends of the sleeves support the bearings and the wheels. The sleeves go in beyond the spring-seats where the car's weigh rests. This much for strength.

Then somebody said, "Why not run the sleeves in to the central opening in the differential housing, just to make pockets that will retain the oil?" Why not?

Oil doesn't get to the brake lining—stays where it's needed, in the housing

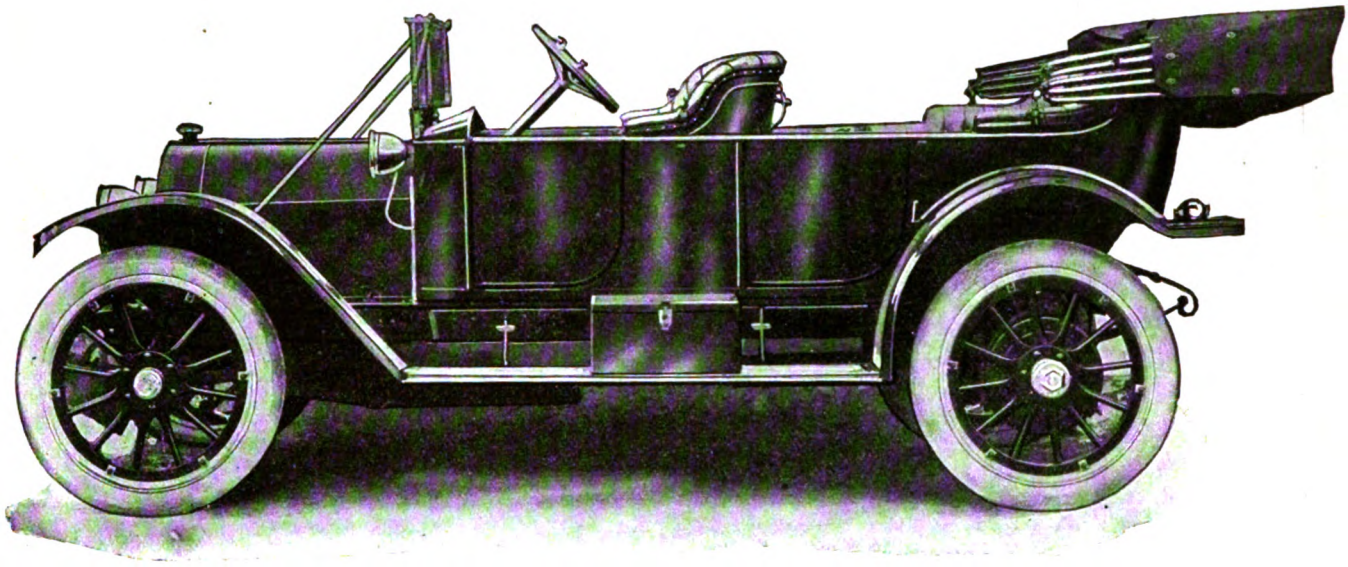
And that's what we did. Look at the picture. The oil is thrown to one side by centrifugal force when the car rounds a curve.

The Timken pocket catches the oil and holds it—all of it—till the car goes straight and gravity returns it to the differential.

That's all there is to it. Simple as standing an egg on end—when you know how.

Yet it does the work, prevents soaked brake linings, saves oil, insures ample oil at the gears.

Its very simplicity and efficiency make it such a natural kind of development in the Timken-Detroit Axle.



The Timken-Detroit Axle Company

Detroit, Michigan, U. S. A.

The only axle manufacturer licensed to make axles equipped with the famous Timken Roller Bearings

Intelligent Distribution

Do You Go After the Prospect or Does He Come to You?
Do You Sell the Car or Does He Buy It? It's Important.

Have you ever stopped to wonder just what will happen when DEALERS will sell AUTOMOBILES along the same modern business methods as employed in the sale of cash registers, typewriters, and insurance?

Isn't it a fact that a large percentage of DEALERS actually do business on a "Brain memorandum?" How many Dealers have installed a "Possible Purchaser List," a "follow up system" or a "checking list" to keep in touch with competitors' sales?

YOU KNOW all the DEALERS in your territory, the cars they represent and the number they sell. Are any of them employing the selling methods that are even comparable to those in vogue with the sewing machine dealers?

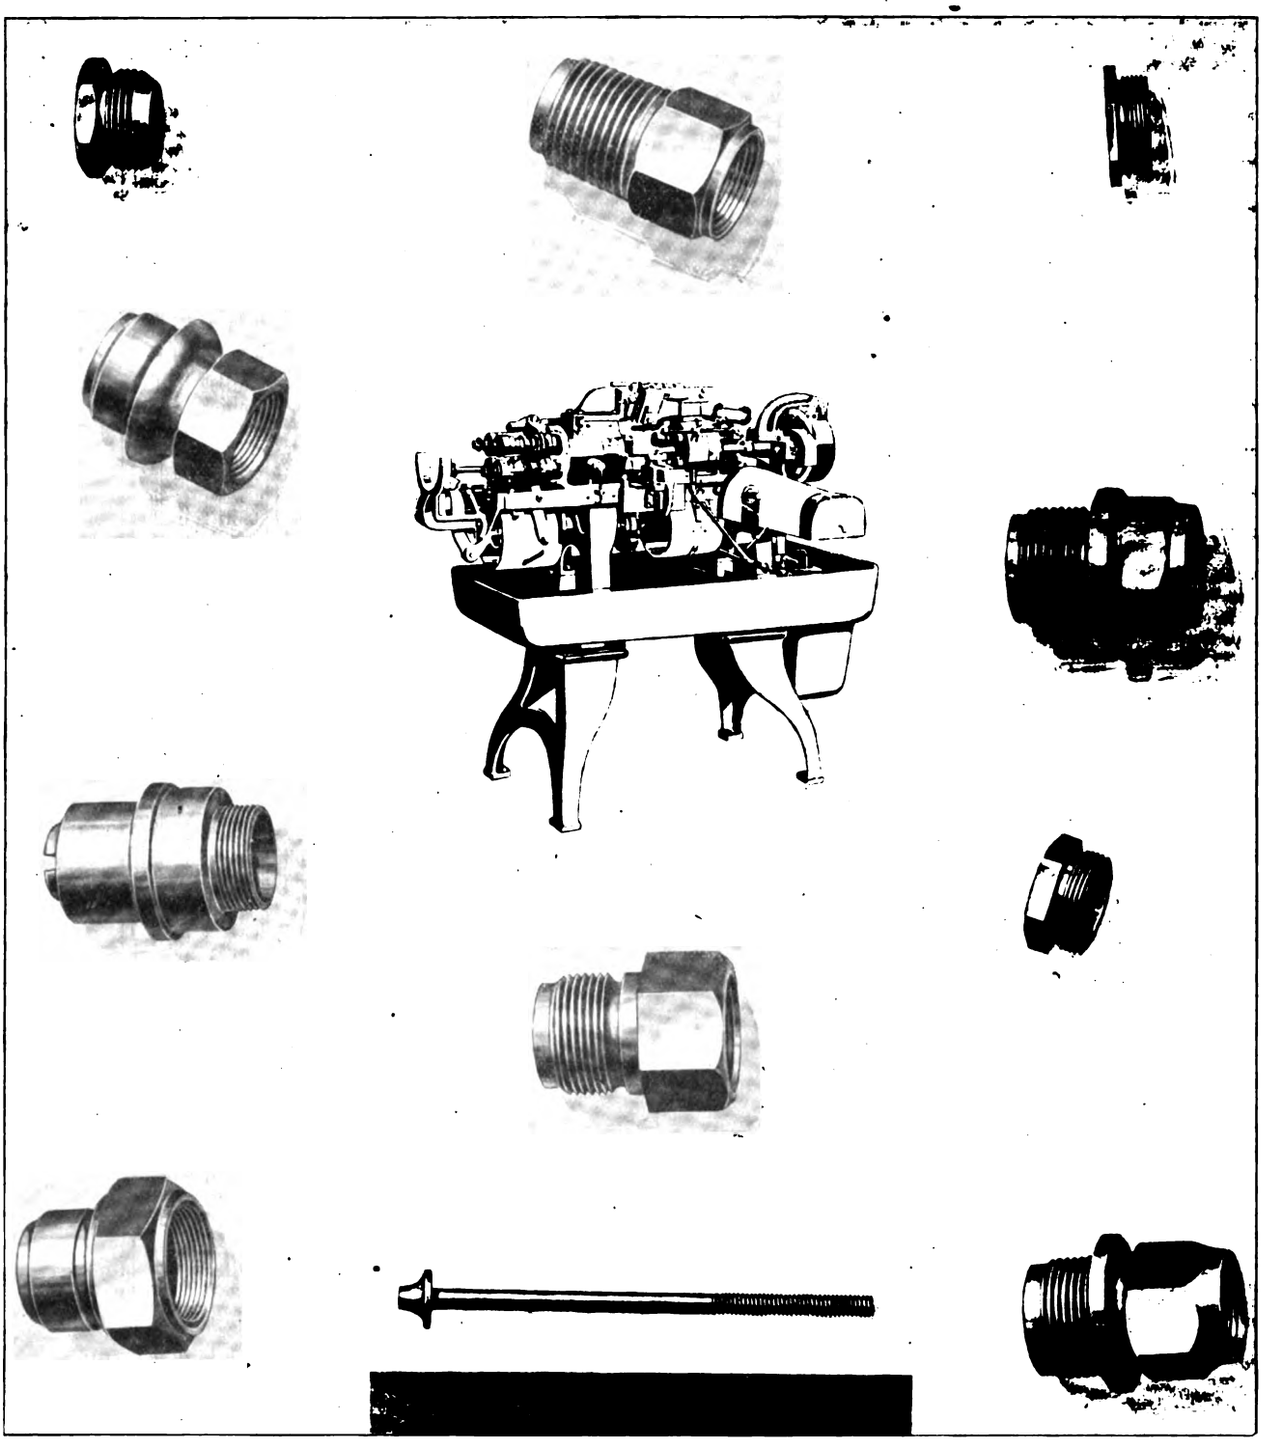
You know the answer—they are doing business along the same lines they would have pursued if AUTOMOBILES were manufactured one hundred years ago. Just waiting for the PURCHASER to drop in and sell himself.

The Above Condition Actually Exists in Every Territory. Some Dealers Are Years Ahead of Others and Are Anxious to Modernize But

IF YOU WERE A PULLMAN DEALER

you would have the backing of the Pullman SALES MAKING ORGANIZATION. A 20th Century distribution department that SHOULD be the 51 per cent. part of any Manufacturing business.

A perfectly developed "PRODUCER" that spends thousands of dollars (our plan on request) to locate your possible purchaser, to get you in touch, to separate the "live prospects" from the "maybe's."



BRIEFLY—We are building 500 extra PULLMANS for 1913. Fifteen hundred in all. Our present Dealers have spoken for 1000 and the increase is for new territory—possibly yours is open.

For 1913 We Offer Three New Models—All Fully Equipped

4-36—$1675 4-44—$2150 6-66—$2750

The Michigan "40"

Wants More Dealers

This year the Michigan "40" will take its place in the very front rank among advertised cars.

It has taken four years to get ready. During that time we have gathered around us some of the ablest men in this line.

We have put out 5,000 cars, and carefully watched their performance. We have made in four years some 300 improvements.

We have equipped an up-to-date factory, with 1,200 employees, and 600,000 square feet of space. So we have an easy capacity of 150 cars weekly.

And we now have a car, at a modest price, with which the right dealer can easily outsell any other car in its class.

We now seek that right dealer in every section not closed.

Designed by Cameron

Our designer-in-chief is W. H. Cameron, for years the chief engineer of the Overland. There is not a more competent engineer in America.

Under him are experts of the highest order, in charge of every detail.

The Michigan "40"—the 1913 model—is the very last word in modern designing. Its equipment is complete and attractive, including electric lights and dynamo. Its tires are oversize—35x4½ inches. It is built with four forward-speed transmission, the most perfect ever designed. Its lines are impressive. Its finish and upholstering have never been excelled. Its price is far below any other car in its class.

We can't publish the details until our big announcements are made, but we will go into complete details with every dealer, and better yet, show him the car.

Bodies by Campbell

The bodies for this new model are designed by John A. Campbell, famous in this line the world over.

Mr. Campbell is one of the few recognized masters in the designing of vehicle bodies. The finest equipages of the late King of England were of his designing. So with the Sultan of Turkey.

Many of the most distinguished families in Europe and America have long given preference to Mr. Campbell's designs.

Mr. Campbell is now in our exclusive employ.

All of his exquisite skill has been brought to bear on the Michigan "40." You never have seen a car which surpassed it in simple elegance, distinction and grace.

Advertised by Hopkins

Our advertising appropriation for the coming season is $350,000. This will place the Michigan among the three biggest advertised cars in America.

This advertising will be handled by Lord & Thomas, who have handled nearly all of the greatest successes made in advertising automobiles.

George H. Daugherty, formerly head of the copy department of Lord & Thomas, will direct this campaign from our office.

C. C. Hopkins, Vice-President of Lord & Thomas, will personally write the copy. Mr. Hopkins is the highest-paid man in this field. And his remarkable campaigns on automobiles include five of the greatest successes ever made in this line.

Our Organization

The Michigan "40" has behind it a very rare organization. Its owners have spent over 30 years in successful vehicle building. Our reputation in this line is nation-wide.

The Michigan Motor Car Company is a separate organization, but it is backed by all of the capital and all the experience of the 30-year-old concern.

The Michigan "40" is four years old. It is the product of some of the best brains in this industry. No concern in the line ever took greater pains to gather able men around it. The names we have mentioned indicate that.

Dealers are thus assured that every detail of this business will be handled capably.

The Record to Date

We have sent out in test territories 5,000 Michigan cars, to be sure of our ground before we undertook this expansion.

Last year in these test territories the Michigan probably outsold every car in its class.

550 were sold in the Pittsburgh district alone. Our home city took 70. Portland, Ore., took 162.

On that same basis, the country over, the Michigan would have been the dominant medium-priced car.

The new model Michigan is immensely better. We are bringing out this season some seventy improvements. This, with our present capacity, organization and advertising, puts the Michigan in the front rank at once.

A Great Opportunity

This means for one dealer in every locality a very rare opportunity.

It means a car which, on simple comparison, will easily outsell any other car in its class.

It means a coming car, backed by money and ability—by efficiency and experience—by a 30-year record for making good.

It means an advertised car, where nine-tenths of the selling is done for the dealer, and done with the highest ability.

It means a car which every possible prospect is bound to come and see. And the price—under $1,600 with complete equipment—will make competition difficult indeed.

Our advertising begins September 1, with double-page spreads in all leading mediums. By that time we want nation-wide distribution. So immediate action is necessary.

We invite immediate- correspondence from capable dealers. Or better still, come to our factory at once. Write or wire for an appointment.

The Michigan agency has a money value. And it is the only great agency that isn't sewed up in nearly every center.

If these facts appeal to you, act—now.

Michigan Motor Car Company, 259 Lay Blvd., Kalamazoo, Mich.

1/4 MILLION

EXHAUST TUBES IN TWELVE MONTHS

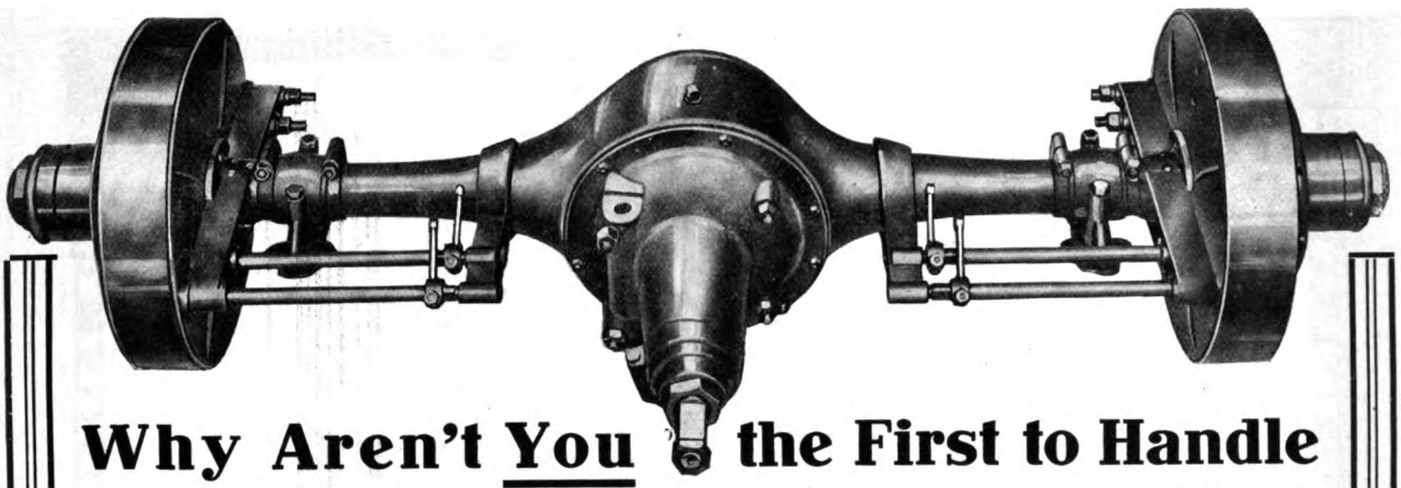
We made this enormous quantity because we received orders for them. We received orders for them because we can make them better, cheaper and quicker than any one else.

We make them better because we have the most up-to-date machinery and employ only expert workmen.

We make them cheaper because we make our own tubing and make so many.

We make them quicker because we know how to make them and do not fuss, fret or fume if the job is new or a "sticker."

Our tubes are strong, accurate to dimensions and very light in weight.



It is not foolish to make your own tubes, but it's futile, especially when you can get what you want without wandering.

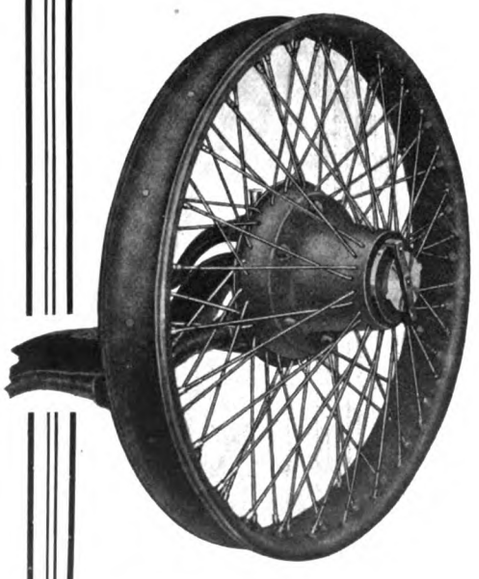
Why Aren't You the First to Handle Wire Wheel Equipped Cars in Your City?



Wouldn't you rather be the leader with all the other dealers following you than to hold off now and later on admit that the other fellow was ahead of you?

Wire wheels have come. Don't make any mistake about that. They are here to stay just the same as they are abroad, where the vast majority of real cars are wire wheel equipped.

Just as it has always been, so it will always be, with wire wheels as with every other development; a few of the "progressives" will "set the pace" and "the rest of the gang will follow."

You must realize that any accessory or improvement which means practically 70 per cent more tire wear is a God-send to you because it is bound to stimulate the sale of cars.

This Is Where the Dealer Plays the Important Part

You are the boy that feeds the manufacturer.

It is your customers' money that he is spending.

If you insist upon his putting wire wheels on the cars you sell, wire wheels will be put on those cars. It's up to you to be a "progressive" dealer and see that your customers' money is well spent.

Don't weaken! You can have wire wheels if you have the backbone to fight for them. If you can get them and get them first you are going to clean up in your territory just as sure as fate. If you don't think you can do this yourself, write us and tell us you want wire wheels on the cars you handle and we will go to the mat for you good and strong.

Remember this, that McCue axles and McCue wire wheels are synonymous with the greatest advancement in the automobile industry.

McCue axles are so built as to permit of either wire wheels or wooden wheels on the same spindle. This simplifies the manufacturing problem greatly.

"The Horn that's Made for the Discriminating"

TUTO HORN

THE TWO TONE HORN

Sound Projects Ahead.

THE primary purpose of the warning signal on a motor car is to notify others of its approach.

¶ All of the sounds that are projected to the side and rear of the car are not only wasted energy, but offensive to everybody for which they are not intended.

¶ The TUTO Electric Horn is so designed and constructed that practically all of the sound is projected straight ahead, where it will do the most good, consequently, giving the very highest operating efficiency that it is possible to produce in a warning signal device.

¶ This projecting action of the TUTO horn is so effective that very little of the sound can be heard by the occupants of the car. To the uninitiated, this may be misleading, especially when comparison is made with other types of horns which are so constructed and mounted as to make as much noise in the ears of the car occupants and those at the side and rear of the car, as for the people ahead where practically all of the sound should be projected.

¶ This straight ahead, efficient action of the TUTO Horn makes it most desirable for standard equipment on any motor car, as it does its work with the least possible disturbance to car occupants and others not concerned in the sounding of the signal. It is this important advantage, together with the double service feature of the TUTO Horn—a low note for regular service purposes and a loud note for emergencies—which makes it the best warning signal device for standard equipment.

¶ Discriminating users now demand the TUTO Horn in preference to all others. You can get it on your new car by simply specifying that it shall be TUTO equipped.

Warner AUTO-METER

THE WARNER AUTO-METER is to the automobile world what U. S. Government clocks are to the nation.

Practically every prominent automobile manufacturer has contracted for the Warner Auto-Meter for his 1913 equipment. We have signed contracts for the equipping of more than 100,000 new cars.

This official recognition of the Warner Auto-Meter comes after eight years ruthless competition with cheaper instruments. The Warner Auto-Meter is chosen despite its highest price.

The Warner Auto-Meter will replace some other instrument on more than 100,000 new cars. The other instruments must be inferior. The verdict of the representative makers is final.

Priced from $50 to $145. For sale at our own branches and leading dealers the world over.

Handsome catalogue on request.

Ford Dealers Read This Then Act!

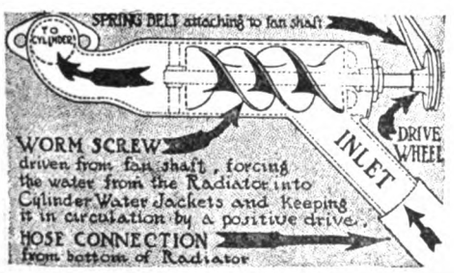
Every Ford owner in your territory will be interested clear to the buying point. Hundreds of dealers will back this statement.

It changes the Thermo Syphon System to force circulation, and the small illustration tells the story of engine efficiency on hot days.

The Ford Water Circulator

forces the water through the cylinder water jacket by the positive drive of the worm screw, insuring rapid circulation with mechanical pressure back of it, giving

A Cool Motor Always



The Ford water circulator can be installed in twenty minutes without boring or reaming. The worm screw shaft is driven off a split pulley on the fan shaft, through a spring belt that snaps on in an instant.

Always in motion when engine is running—practically no excess power required to drive—does not impede circulation when motor is at rest.

"Furnish Ford Owners With This Cooling System"

It saves engine wear and tear, promotes speed—saves repairs—economizes on oil—prevents carbon—comes to you ready to install—weighs but three pounds—cast aluminum.

In the Otho System

THE FINAL SOLUTION OF

Self Starting
Lighting
Ignition
Signalling

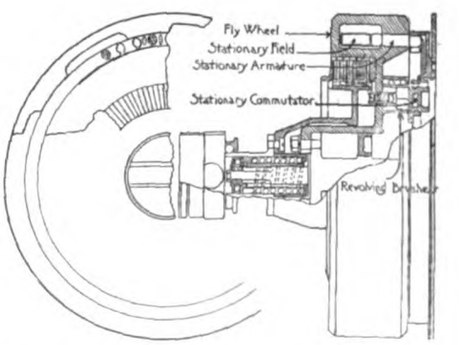
"Is right" Inside the Flywheel

The finality of simplicity—the last word in modern electrical engineering as applied to automobiles—the only self starter that turns the engine 75 R. P. M. right from the start, spinning it indefinitely.

Power plant stores current as needed—enough for the starter, for lights, ignition and, if necessary, for heating.

Built right in the fly wheel(which, by the way, is the only moving part of the appliance), simple, strong, never out of order, always ready.

No complicated or moving wiring, no gears, clutches, shafts, chains, or, in fact, any other complication.



The Otho system generates its own power—then uses it, in a mechanically and electrically perfect way, it being directly attached to crank case, acting on the fly wheel, and not connected by belts or gears.

This is our introduction to a story that is going to be of out-of-ordinary interest to every manufacturer who sees the keen need for a device that will furnish a powerful, natural starter with a reserve supply of current ample to meet every requirement in the way of lighting, ignition, and signaling.

Succeeding advertising, with detail illustration, will go further into a description of the Otho system.

We want to go into this matter with car manufacturers, because we kno wthat this system will prove to be the most radical and improved refinement ever put upon an automobile.

Engineers, designers and purchasing agents will do well to communicate with us, sending as a preliminary measure, blue prints covering engine construction.

THE OTHO MOTOR COMPANY, 60 State Street, Boston, Mass.

THE MOTOR WORLD

Vol. XXXII New York, U. S. A., Thursday, August 1, 1912. No. 6

MAY SETTLE DYER PATENT SUITS

Negotiations Pending Between Patentee and Board of Trade—Latter May Obtain Licenses for All its Members.

Unless a hitch develops, it is probable that, save for certain legal formalities, the last has been heard of the suits brought by Leonard H. Dyer, who comprises the Enterprize Automobile Co., of New York, against the Locomobile Co. of America, Winton Motor Carriage Co. and Maxwell-Briscoe, Inc., and which charge infringement of the Dyer patents, Nos. 885,986 and 921,963, which cover the direct drive and sliding gear now in general use. For, while all of those concerned are close-mouthed, it is known that negotiations are in progress looking toward not only a peaceful settlement of the litigation but toward the issuance of licenses which will safeguard from similar proceedings all other members of the Automobile Board of Trade.

How far the negotiations have progressed, however, cannot be ascertained, but indications make it appear that both sides are favorably disposed. The patent experts of the Board of Trade have realized that the Dyer patents are of far-reaching character, while the Dyer interests are not insensible of the fact that recognition of their rights by such an important and influential organization greatly will strengthen their position and enable them to proceed with vigor against the many manufacturers who will not be affected by the pending settlement.

The suits against the Locomobile, Winton and Maxwell-Briscoe companies have been pending in the Federal court in New York for some 20 months, but repeated extensions have served to delay the taking of testimony and, to all practical purposes, the litigation has not made material progress. Who or what were responsible for the negotiations looking towards a peaceful settlement is a matter of conjecture.

As the Motor World has stated on several previous occasions, the predecessor of the Board of Trade, the Association of Licensed Automobile Manufacturers, in 1905, purchased five Dyer patents which have to do with various functions of the transmission system. It supposed that thereby it had fully protected its members from litigation involving any of Dyer's patents, but in 1910 Dyer, operating as the Enterprize Automobile Co., brought to bear the two patents which now loom so large as to be almost a controlling influence in the industry, Nos. 885,986 and 921,963, which in 1905 had not been issued, although they were pending in the patent office. The intimation has been let fall that when the Dyer interests were negotiating the transaction in 1905 with the A. L. A. M., realizing their controlling character, they "held out" the two unissued patents, and it was understood that this allegation would form a part of the defense in the Locomobile, Winton and Maxwell-Briscoe suits. A peaceful settlement, such as now is promised, will render unnecessary the washing of that piece of linen. But it will not serve to protect other than the members of the Board of Trade, nor will it affect the many suits which Dyer has brought against individual owners.

Knapp Assumes Abbott Presidency.

F. M. Knapp, of Warren, Pa., has been elected president of the Abbott Motor Co., of Detroit, to fill the vacancy caused by the death of C. W. Jamieson. M. M. Preston, also of Warren, who was second vice-president of the company, has been made vice-president, which office previously was filled by Knapp. F. B. Jamieson, of Warren, manager of the Jamieson estate, has been elected a member of the board of directors. As the new president conducted the affairs of the Abbott company during the long illness of Mr. Jamieson, he, therefore, is in no wise strange to his duties.

More Tires Coming from Providence.

The Bourne Rubber Co., of Providence, R. I., is making ready to engage in the manufacture of automobile tires. Heretofore it has devoted itself to the production of rubber sundries.

NEW MEN ENTER LOZIER COMPANY

Jewett Takes the Presidency and New Yorker Becomes Treasurer—Lower-Priced "Six" to be Featured.

After a long period of that unhappiness which comes of operating a large corporation with stinted working capital, the Lozier Motor Co., of Detroit, finally has reached the turn in the lane which points the other way. The change of affairs was brought about late last week, when Harry M. Jewett, one of the most successful coal operators in the West and the head of the Paige-Detroit Motor Car Co., succeeded Harry A. Lozier as president of the company; he, however, retains his office in the Paige-Detroit company. At the same time, Raymond B. Fosdick, of New York, was elected vice-president and treasurer and E. P. Earle and H. E. Kahler, also of New York, were added to the Lozier board of directors, the new men bringing with them new money, which, with their undoubted ability, scarcely can fail to exert immediate influence.

President Jewett has worked wonders in the Paige-Detroit company in about 18 months, having brought it to a stage of unwonted prosperity, while Fosdick, the new treasurer, although strange to the automobile business, is a deep delver and thorough reorganizer, whose ability in those respects has been amply demonstrated in New York City, where he has served as the Mayor's commissioner of accounts, or official prober. Harry A. Lozier, the former head of the Lozier company, will remain a director of the company, but will be relieved of the burden of business cares which has brought about a nervous condition and left him in poor health generally.

When, about two years ago, the Lozier company removed from New York to Detroit, it acquired a large accession of Detroit capital, which at the time was badly needed. The renewed affluence was of only a temporary character, however, and during recent months rumor has been free

Digitized by Google

with Lozier affairs. Two months since reports had it that Henry Ford had purchased, or was about to purchase, the Lozier plant, which, so far as ascertainable, was based on a statement that the Lozier property had been offered to Ford, who, however, purchased no part of it. Soon afterward the Lozier company liquidated many of its old debts, which fact made appear that new money had been forthcoming from some sources, which sources, according to apparently trustworthy accounts, were two immensely wealthy directors of the Lozier company, who provided $500,000 in consideration of Lozier's turning back into the treasury one-half of the stock which he held, which action placed them in control.

That the affairs of the company were approaching a climax was indicated on Saturday last, when an attachment against it was filed in New York by the Merchants' National Bank of New York on a note for $25,000, due July 25th, of which but $2,919.70 had been paid. Reflecting the reorganization which had been effected in Detroit, on the same day the attachment was vacated and the action discontinued.

Heretofore the Lozier company has concentrated its effort on a 50-horsepower, six-cylinder model listing at $5,000, although it was known that a "little six" was in preparation. The latter now is well in hand and the most will be made of it by the new management. It will be styled "Type 77, Light 6," and is referred to not only as a "self-starter" but a "self-seller." Its cylinders are 3⅝ x 5½ inches, developing 36 horsepower. In addition to an engine starter, its equipment includes the Gray & Davis dynamo lighting system, a speedometer, clock, electric horn, top, windshield, extra demountable rim, tire holders, etc. It will list at $3,250, and in lines and appearance closely follows the Lozier "big six."

Wishart-Dayton Thrown into Bankruptcy.

Although the Wishart-Dayton Auto Truck Co., of 501 Fifth avenue, New York City, was supposed to be financially sound, if for no other reason than that it was sponsored by George Wishart, father of Spencer Wishart, the Mercedes racing driver, a receiver was appointed for it yesterday in Federal Court in New York City upon the petition of William Farnum, Eugene C. Ludin and James H. Rooney, whose claims for services aggregate $961.02. They allege that the concern has been insolvent for some time and has made preferential payments and other similar moves. Including a claim of $7,000 by the Dayton Auto Truck Co., of Dayton, O., the liabilities are said to be $9,000 or $10,000, while the principal assets are one Dayton and one Ohio truck, together valued at $5,000. The petitioners, however, allege that the furnishings of the office, together with the trucks, have been moved and secreted, and the creditors ask the court to unearth the assets that their claims may not be rendered worthless.

DISCO TO MAKE ELECTRIC STARTER

Detroit Company Makes an Unexpected Move—Gas Starters, However, Will Remain its Chief Production.

Indicative of its intention to meet all demands and to maintain its position in the trade, the Ignition Starter Co., of Detroit, has completed arrangements for the manufacture of an electric lighting, starting and ignition system, which decision undoubtedly will serve to create widespread surprise, as it was supposed the company was wedded to the gas starter.

The electric system will bear the title Disco, but its manufacture does not portend that the Ignition Starter Co. will devote less attention to the well-known Disco gas starter. It means chiefly that the Disco people have elected to so position themselves as to respond to all calls. They already have placed orders for necessary machinery and equipment, and are negotiating for a factory building in Detroit which will afford 100,000 square feet of floor space. In addition to the gas starter, they are planning to build 12,000 of the electric devices for the season of 1912-13, the delivery of which will begin about September 1st.

"In adding the electric system to our line," said George P. Sweet, general manager of the Ignition Starter Co., in speaking of the matter, "we wish it distinctly understood that we are by no means abandoning or sidetracking the Disco gas ignition starter, which we will continue marketing in larger quantities than before. Our contracts for 1912-13 on the Disco gas starter greatly exceed in volume our 1912 business, but there is a demand for an electric starter and lighter of a very high grade, and we have been working for months in the development of our device. It probably will be the highest priced electric starting, lighting and ignition system on the market. Our plans are so thoroughly perfected that we will back the Disco electric system with the broadest service guarantee that the trade ever has known."

Petition Halts Kayton Amalgamation.

The Kayton Taxicab and Garage Co., of 174 East 73rd street, New York, has been petitioned into bankruptcy by the American Taximeter Co., whose claim amounts to $1,866. It is alleged that the company is insolvent and has made preferential payments to the amount of $500 and transferred merchandise and accounts of the same value. Its liabilities are $30,304 and its assets, which include 63 cabs, $13,488. The company was incorporated in February, 1908, with $100,000 capital stock, which, during the following year, was increased to $200,000. About a year since the Kayton company distinguished itself by instituting a reduced fare service during certain hours of the day, which, however, proved a failure. Negotiations looking towards its amalgamation with another company have been in progress, and the petition in bankruptcy therefore places a value on its goodwill and asks that the court take cognizance of the situation in order that the merger may be consummated, if possible.

Toledo Tire Chain Makers Reorganize.

The Walker Chain Mat Co., of Toledo, O., has been reorganized under the style Walker Tire Chain Co., capitalized at $150,000. The officers are as follows: H. F. Rohrman, president; Hugh Williams, vice-president; Maurice A. Carter, treasurer, and Charles A. Newman, secretary. Among the stockholders, it is stated, are John A. Dix, governor of New York, and William Huppuch, chairman of the New York Public Service Commission. As its name implies, the company will manufacture a non-skid tire chain grip. Its offices are located in the Ohio building in Toledo, an assembling plant being maintained in the Factories' building at 12th and Woodruff streets, in that city.

Buffalo Electric to Have Two Plants.

The Buffalo Electric Vehicle Co., which recently absorbed the Babcock electric, among other properties, has acquired the entire building at the corner of Main and Barker streets, Buffalo, N. Y., previously occupied by the Denniston Co., whose financial embarrassment, it was stated, indirectly was due to the merger. The Denniston Co. used the building for the construction of automobile bodies, but the Electric vehicle company will utilize the upper floors for the making of pleasure cars and the main floor as a salesroom. The Babcock plant on West Utica street will be devoted to the manufacture of commercial cars and an electrically-driven baggage truck.

Walpole Acquires a Second Factory.

Its plant at Walpole, Mass., having proved inadequate to meet the demand for its tires and other rubber goods, the Walpole Rubber Co. has acquired a factory at Foxboro, five miles distant, previously occupied by the Van Choate Electric Co., in which the manufacture of Walpole tires will be concentrated. The Foxboro plant comprises a group of buildings having more than three acres of floor space, and is being equipped to produce 500 tires per day; its ultimate capacity will be twice that amount.

Kelly-Springfield Sues Out Attachment.

Because of a 30-day note which went to protest, the Kelly-Springfield Tire Co., on Friday last, 26th ult., sued out a writ of attachment against the United States Motor Co. for $2,512.50, which represents a balance unpaid. The action is akin to several others which have been filed against the big corporation, which is undergoing reorganization, and did not serve to affect it in any way; it will be taken care of in due course.

PALMER & SINGER TO FIGHT DECREE

Their Default in Dyer Suit Proves Surprise to Them—Fine Points of Legal Procedure Now an Issue.

Despite the records of the United States District Court for the Southern District of New York, which show that a decree pro confesso has been ordered against the Palmer & Singer Mfg. Co., of New York, in the action brought by the Enterprize Automobile Co. for infringement of the Dyer patents, Nos. 885,986 and 921,963, Palmer & Singer have no intention of abandoning the fight. They first learned of their default only when the Motor World, which exclusively contained the information, reached them last week, when they immediately took action to intervene and to prevent the issuance of an injunction; they state that they have every intention of fighting the case to a finish.

For the time being, however, the matter has resolved itself into a more or less personal controversy between the lawyers representing the opposing interests over certain points of legal procedure. Whether the Palmer & Singer attorney at the present has the right to demur to the bill of complaint is one of the contested points. He secured several extensions of time for answer, and on the last day of the last extension filed a demurrer, instead of an answer; the Enterprize attorney, however, chose to regard this demurrer as a nullity, holding that such a document could not be filed because no extension of time had been granted for the purpose, and, failing to find the answer on record, he moved for and secured the decree pro confesso. The defense claims the demurrer may be filed at any time prior to the entry of the decree pro confesso, and also maintains that the demurrer raises a question as to the validity of the Dyer patents, which question will have to be adjudicated. There is also the contention that the order signed by Judge Hand was made without notice to the defense and in "disregard of a demurrer properly filed in court."

The thirty days from the granting of the decree expire about August 16, and the Enterprize company then must give notice to the Palmer & Singer company that it will move for an interlocutory decree, which would entitle the complainant to damages, but the defense states it will oppose every step and considers the case as being very far from finished.

Lamp Company Brings Infringement Suit.

Alleging that the Knickerbocker Brass Goods Co., of New York City, has infringed one of its patents on a vehicle lamp, the Victor Lamp Co., of Cincinnati, O., brought suit on Monday last, 29th inst., in United States District Court for the Southern District of New York asking an injunction and damages. The complainant states it believes the damages will amount to $10,000 and names that amount in its pleadings. The patent in question, No. 980,493, was issued to William J. Corcoran, of Cincinnati, January 3, 1911, and was assigned to the lamp company. It covers a catch whereby the oil receptacle in a kerosene lamp is attached to the lamp proper. At the Knickerbocker offices it was said that lamps of this description had been made by the company and sold to the automobile trade, but that as soon as it was learned that the device was patented the manufacture was discontinued.

Rutenber to Continue Both Plants.

Reports to the contrary notwithstanding, the $1,350,000 Rutenber Motor Co., which recently took over the Western Motor Co., of Marion and Logansport, Ind., will continue to operate both plants. The foundry and the aluminum and brass works will remain at Logansport, and the manufacture of the other parts which go to make up the Rutenber engine will be performed at Marion, as at present. New machinery will be added and outputs of both plants considerably enlarged. As the Motor World stated last week, George W. Bowen, of the Bowen Mfg. Co., of Utica, N. Y., has assumed the presidency of the Rutenber company, in which he has acquired a large interest. J. W. Stepenson is treasurer and A. C. Barley is secretary of the new corporation.

Two Final Decrees Are Awarded to Weed.

Suits brought in United States District Court for the Southern District of New York by the Weed Chain Tire Grip Co. against the Newhall Chain Fore & Iron Co. of New York City and the Seneca Chain Co. of Mansfield and Kent, O., for infringement of the Parsons patent, No. 723,299, were ended yesterday, when final decrees were awarded the Weed company by consent of both parties. The actions were commenced about two years ago and were contested by the defendants until the matter reached the settlement stage. The Newhall company, before it was made the object of a preliminary injunction, made the Everready and Presto grips, while the Seneca company manufactured cross chains for manufacturers and the general trade.

Vincent now Packard's Chief Engineer.

J. G. Vincent, formerly of the engineering staff of the Hudson Motor Car Co., of Detroit, has been appointed chief engineer of the Packard Motor Car Co., of that city, and already has assumed the duties. With S. D. Waldon, vice-president of the company, he is about to set out for a long trip in the Packard "little six," which practically is ready for the market. The new model is slightly smaller and lighter than the present Packard "six," which lists at $4,850, and will sell for $4,150, completely equipped. It is expected that deliveries will commence about November 1st.

SALE OF ATLAS PLANT POSPONED

Delay Granted on Plea of Prospective Bidder—Flanders Interests also Seek Property—Knight License Involved.

Because a prospective purchaser who looks promising had not inspected the property or examined the appraisement, and therefore was not quite ready to submit a formal bid, the sale of the plant of bankrupt Atlas Engine Co., of Indianapolis, Ind., did not occur on July 29, the date fixed by the court. Instead, it was postponed until August 12, although the intending purchaser is not certain he will be in position to comply with the terms even on that date.

He is M. L. Thomsen of Cleveland, Ohio, professedly representing the Baldwin Locomotive Works of Philadelphia, which is an Atlas creditor, but who is supposed to represent others whose identity is well concealed, as is their purpose in seeking to acquire the plant.

Whoever they may be, it is their purpose to organize a company, and, according to Thomsen, they are well able to purchase the plant and finance the undertaking.

He submitted a sworn statement, in which he avers that the bidder he represents will pay $25,000 more than the upset price, $80,000, named in the court's order of sale, and assume the principal of $1,050,000 worth of outstanding bonds, besides paying off several other mortgages.

Unless the Thomsen people submit a bid, it is probable that the Atlas property will pass into the hands of the Flanders interests in Detroit. Not the Flanders Mfg. Co., of which he is president, nor the Everitt Motor Car Co., in which circumstances require him to appear a more or less silent partner, so to speak, have tendered a bid for the plant, but an offer has been made by W. E. Flanders and B. F. Everitt, of Detroit, who say they desire to use the Atlas plant for the manufacture of automobiles, which, it is well understood, will be Everitt cars, as in order to carry out their plans and to attain the output of 16,000 Everitts, which they have in view, it is absolutely necessary that a plant of some sort be secured somewhere without much delay. The Flanders-Everitt interests agree to pay the interest on the Atlas bonds, but did not agree to assume the principal, which means if their venture proves successful the bondholders will lose nothing, while if it failed they will receive only what may be realized from the sale of the property, which conditions make the promise held out by Thomsen much more attractive and worth waiting for.

Not the least interesting situation brought about by the Atlas failure concerns the future manufacture of Knight engines for the trade at large. The Atlas company is possessed of the only Knight li-

Digitized by Google

cense of that sort, and several manufacturers who have announced Knight-engined cars, other than the three who are privileged to manufacture their own engines, have been depending on the Atlas factory for their power plants. Unless the successful bidder for the Atlas Engine Works continues to produce Knight motors, these several manufacturers will be left badly in the lurch. The Knight license, which cannot be sold separately, is among the assets of which the successful bidder will become possessed. The same is true of the rights to the Atlas-type Diesel engine.

According to the receiver's appraisement of the Atlas property, its valuation is $1,356,723, made up as follows: Cash on hand. accounts, etc., $234,905; buildings, $518,056; real estate, $117,600; machinery, $351,845; sprinkling and water system, $50,000.

Court Orders Sale of Mais Plant.

August 19th has been set by the Federal court as the date for the sale by the receiver of the assets of the Mais Motor Truck Co., of Indianapolis. A condition of the sale requires payment of at least one-third in cash. In round figures, the assets of the bankrupt company are $250,000. The liabilities, including notes given for new capital, approximate the same amount. Included in the assets are several trucks which are practically completed, machinery and real estate, the value of which is more than $200,000, listed at original cost.

Wise to Market the Touraine "Six."

S. J. Wise & Co., of New York, who hitherto have handled the Amplex car in the eastern half of the country, are having built for them by a well known eastern manufacturer a six-cylinder car, which will be styled the Touraine and which will be marketed under the firm's name. It will list at $2,950, fully equipped. In addition, Wise & Co. will handle the Paige-Detroit as a popular priced model.

Keetons To Be Reproduced in Canada.

Keeton Motors, Ltd., is the title of an offshoot of the Keeton Motor Car Co., of Detroit, which has been organized in Brantford, Ont., where a factory has been acquired and where Keeton cars will be reproduced for the Canadian trade. The new company is capitalized at $200,000 and is reported to include in its make-up some of the members of the powerful Massey-Harris Co.

General Motors Anticipates Its Loans.

Having anticipated payment of all of its loans, and reflecting its condition, the General Motors Co. is now preparing to pay to the Central Trust Co., of New York, as trustee of its 6 per cent. first lien note issue, $1,000,000, which will be applied for the redemption of notes to the value of $1,500,000, which are payable to the trustee. These notes do not fall due until October 1st.

MEN WHO HAVE SHIFTED POSITIONS

Resignations and Promotions That Served to Place Many Workers in New Places —Few Leave the Trade.

W. J. Lawrence has been appointed manager of the Minneapolis branch of the Moline Automobile Co., of East Moline, Ill. Previously he was connected with the Studebaker branch in that city.

William J. Slater has been appointed assistant sales manager of the Michigan Buggy Co., of Kalamazoo, Mich. Formerly he was advertising manager of the Firestone Tire and Rubber Co.

J. V. Hall has been appointed sales manager of the Olds Motor Works, of Lansing, Mich. Previously he was manager of the Olds branch in Chicago. He succeeds to the vacancy caused by the resignation of Rupert E. Paris.

S. Henderson, for the past year chief inspector for the Studebaker Corporation, has resigned that position to join the Everitt Motor Car Co. He will have charge of the Everitt service department which is to be established in New York City.

E. Q. Cordner, who has been sales manager for the American-Marion Sales Co., of New York, since its organization, has resigned to become manager of agencies for the R. & L. Co., of New York, general Eastern distributers of the Garford product.

L. E. Kraft has been appointed manager of the Cadillac branch in Kalamazoo, Mich., to fill the vacancy caused by the resignation of H. M. Gilbert. Previously, and for a number of years, Kraft has been connected with the Cadillac agency in Detroit.

James F. Kennedy has been appointed a travelling representative of the Goodyear Tire & Rubber Co., of Akron, O. He will circulate in the States of Pennsylvania, Ohio, Indiana, Kentucky and Tennessee, making the Goodyear motor tire his specialty.

Raymond Cavanagh has been appointed advertising manager of the Moline Automobile Co., of East Moline, Ill. He has had wide experience in the advertising field, having at various times been connected with well-known advertising agencies in Chicago.

Frank B. Hart has been appointed manager for the Simkin Mfg. Co., of Chicago, manufacturers of the Daisy lighter, which company is undergoing reorganization. Hart for years was identified with the Excelsior Supply Co. of Chicago, where he is well known.

Frank A. Groves, president and general manager of the Speedwell Motor Car Co. of Illinois, has been appointed sales manager of the parent company of that name in Dayton, O. Groves is not strange to Dayton, where for years he was identified with the National Cash Register Co.

M. A. Sacksteder and C. H. Potter, respectively manager and assistant manager of the United Motor Dallas Co., have resigned those positions in order to engage in the automobile business in Dallas, Tex., on their own account. They are organizing a company, which will be styled the American and Marion Co., and will handle cars of those names.

E. B. Fleisch, general manager of the Long Mfg. Co., of Detroit, makers of radiators, has resigned that office, and it is understood that he will return to the railway supply business, in which he previously was engaged. His duties will be divided among various offices of the company. J. L. Dryden is now looking after the sales and advertising departments.

H. E. Shiland has been appointed assistant general manager and director of sales for the Havers Motor Car Co., of Port Huron, Mich. Shiland has been connected with the industry for some twelve years, until about two months ago having been sales manager of the Westcott Motor Car Co., of Richmond, Ind., after having served for years as sales manager of the Buick Motor Co.

Ernest Coler, who has been a member of the John N. Willys staff for some time, has been appointed advertising manager for the Willys group of automobile factories. He will supervise the work of the Garford, Gramm and Willys-Overland companies, making his headquarters at the factory of the latter in Toledo. Before going to Toledo, Coler was assistant advertising manager for the United States Motor Co. in New York City.

C. J. Corkhill has been appointed assistant sales manager of the Cole Motor Car Co., with headquarters in Omaha, Neb. He will have charge of the territory bounded by the Mississippi River on the east, Gulf of Mexico on the south, Rocky Mountains on the west and Canada on the north. J. R. Moler has been given the same title and will have charge of the territory west of the Rockies. He will have no stated headquarters, but will circulate constantly among Cole agents in that district.

To Build Motor Wagons in Maine.

C. H. O'Brien, who was vice-president and general manager of the Kennebec Mfg. Co., of Hallowell, Me., is forming a company for the manufacture of motor wagons. For the purpose, he has purchased the buildings previously occupied by the Kennebec company.

Disputed Top Contract Leads to Law.

As the outgrowth of a disputed contract for tops, suit for $5,000 has been brought by C. V. Taylor, of Pontiac, Mich., against the Studebaker Corporation. Taylor claims $3,500 for goods delivered and asks damages for the rest of the unfilled contract.

THE WEEK'S INCORPORATIONS

Moline, Ill.—John Deere Wagon Co., under Illinois laws, with $500,000 capital; to deal in vehicles, etc.

Sioux City, Ia.—Mandel-Frisch Auto Repair Co., under Iowa laws, with $5,000 capital; to deal in motor cars.

Detroit, Mich.—Detroit Body Co., under Michigan laws, with $1,000 capital; to manufacture automobile bodies.

White River Junction, Vt.—Vermont Cadillac Co., under Vermont laws, with $500 capital; to deal in motor cars.

Oswego, N. Y.—Oswego Essenkay Co., under New York laws, with $1,500 capital; to deal in tire fillers, etc. Corporators—A. P. Murdoch, A. V. Radcliffe, C. C. Place.

Cheek Spring, Va.—Cheek Spring Motor Co., under Virginia laws, with $50,000 capital; to deal in motor cars. Corporators—C. E. Hooper, C. L. Lambert and others.

Indianapolis, Ind.—Indianapolis Tire Co., under Indiana laws, with $300,000 capital; to manufacture tires. Corporators—A. A. McKain, E. J. Holliday, D. M. Parry.

Madison, Wis.—Madison Motor Bus Co., under Wisconsin laws, with $5,000 capital; to operate a motor bus line. Corporators—Fred W. Coombs, Paul Kney, Harry J. Parke.

Grafton, W. Va.—Grafton Garage Co., under West Virginia laws, with $2,900 capital; to operate a garage. Corporators—Henry J. Pracht, H. D. Comerford, Albert Kunst.

San Francisco, Cal.—Little Automobile Co., under California laws, with $20,000 capital; to deal in motor cars. Corporators—W. R. Huff, John Johnstone, J. E. Little.

New York, N. Y.—Oil Converting Co., under New York laws, with $10,000 capital; to manufacture motor devices. Corporators—A. T. Porter, W. D. MacLauren, O. W. Shinn.

Cincinnati, Ohio—Swing Wheel Co., under Ohio laws, with $50,000 capital; to manufacture motor car wheels. Corporators—A. J. Swing, R. E. Werner, R. H. Langdale.

Hudson, N. Y.—Warren Street Garage Co., under New York laws, with $6,000 capital; to operate a garage. Corporators—John F. Hester, Henry B. Hester, Dennis Hester, Jr.

Camden, N. J.—Service Motor Truck Co., under New Jersey laws, with $50,000 capital; to manufacture motor trucks. Corporators—R. S. Smith, C. D. Hackett, E. J. Eldredge.

Chicago, Ill.—Herreshoff Motor Co. of Illinois, under Illinois laws, with $500 capital; to deal in motor cars. Corporators—W. G. Wordingham, Charles H. King, E. G. Lancaster.

Westfield, N. J.—Darby Motor Car Co., under New Jersey laws, with $25,000 capital; to deal in motor cars. Corporators—Levy Douglass Darby, Hatty C. Darby, Aaron B. Darby.

Springfield, Ill.—McDonough County Automobile Association, under Illinois laws; to better road conditions. Corporators—Joseph B. Bacon, T. H. Downing, Edward C. Wolff.

Bridgeport, Conn.—A. L. Schavoir Co., under Connecticut laws, with $3,000 capital; to deal in motor car supplies. Corporators—A. L. Schavoir, Ernest Oliver, Joseph E. Lannon.

Newark, N. J.—Warwick Motor Co., under New Jersey laws, with $125,000 capital; to deal in motor cars. Corporators—James D. Nocel, E. Orton Woodrutt, Merton E. Hidden.

Boston, Mass.—Plymouth Garage and Machine Co., under Massachusetts laws, with $10,000 capital; to operate a garage. Corporators—Adoniram J. Smith, Ruth E. Kingan and others.

Owensboro, Ky.—Ames Motor Car Co., under Kentucky laws, with $100,000 capital; to manufacture motor cars. Corporators—F. A. Ames, Owensboro, and G. W. Yeoman, Detroit, Mich.

Pasadena, Cal.—Pasadena Essenkay Sales Co., under California laws, with $5,000 capital; to deal in tire fillers. Corporators—Alexander Holland, J. C. Hasbrouck, Jr., Etta B. Savage.

Salem, Mass.—Motor Sales and Service Co., under Massachusetts laws, with $25,000 capital; to deal in motor cars. Corporators—George B. Mason, Ellsworth S. Adams, George B. Kinsman.

Cincinnati, Ohio—Acme Motor and Delivery Co., under Ohio laws, with $15,000 capital; to deal in motor cars and operate a motor delivery service. Corporators—William Ernest Minor and others.

Philadelphia, Pa.—Auto Distributers, Ltd., under Pennsylvania laws, with $200,000 capital; to deal in motor casr. Corporators—F. H. Hansell, I. C. Clow, John A. MacPeak, all of 419 Market street.

Cleveland, Ohio.—Knox Rubber and Supply Co., under Ohio laws, with $10,000 capital; to deal in motor accessories. Corporators—R. A. Lang, C. S. Wachner, H. H. Burton, A. G. Dole, F. F. Blaize.

Camden, N. J.—Garrison Gasolene Engine Specialties Co., under New Jersey laws, with $125,000 capital; to manufacture gasolene motors. Corporators—F. A. Kuntz, F. S. Sauerman, F. S. Muzzey.

Paterson, N. J.—Paterson and New York Motor Express Co., under New Jersey laws, with $50,000 capital; to operate a motor delivery service. Corporators—John M. Simpson, Mary Brooks, Henry Smith.

New York, N. Y.—Autodrome Co., under New York laws, with $50,000 capital; to promote motor racing exhibitions. Corporators—Harry L. Curran, Clara D. Curran, Coney Island; Benjamin B. Jones, New York City.

New York, N. Y.—William Strathmann, Inc., under New York laws, with $5,000 capital; to deal in motor vehicles. Corporators—William Strathmann, 2906 Broadway; Herman C. Berkemeyer, John H. Semken, both of 2794 Broadway.

Buffalo, N. Y.—Mutual Motor Car Co., under New York laws, with $12,000 capital; to deal in motor cars. Corporators—Albert Poppenberg, 247 Bryan street; Frederick C. Carter, 4 Fargo avenue; Orson E. Yeager, 419 Richmond avenue.

Esopus, N. Y.—L-M-S Motor Co., under New York laws, with $10,000 capital; to deal in motor cars. Corporators—Herbert Cohen, 140 West 111th street, New York City; Emil Akder, 41 Convent avenue, New York City; Joseph J. Baker, 456 Riverside Drive, New York City.

New York, N. Y.—Standard Automobile Co., under New York laws, with $10,000 capital; to deal in motor cars. Corporators—Earle H. Frichtman, Montclair, N. J.; Henry D. Chapin, 647 Fox street, New York City; Jule L. Janover, 214 West 129th street, New York City.

New York, N. Y.—Automobile Importers' Alliance, Inc., under New York laws, with $750 capital; to deal in motor products. Corporators—George J. Ginsburg, Rutherford, N. J.; Herbert L. Wymer, Rosedale, L. I.; Bernard C. Wymer, 602 West 137th street, New York City; Henry W. Showers, 15 Wall street.

Changes of Corporate Name.

Peoria, Ill.—Starbuck Motor Co. to C. W. Robinson & Co.

Racine, Wis.—Racine Rubber Co. to Belle City Rubber Co.

Washington, D. C.—Bowles Motor Sales Co., to Warren Motor Sales Co.

Bridgeport, Conn.—Eddy Sherwood Carriage and Motor Co. to Jennings Sherwood Carriage and Motor Co.

Milwaukee, Wis.—Luick-Bassett Producer Co. to Sharp-Bassett Gas Producer Co.

ODD OUTGROWTH OF BANKRUPTCY

After Signing Composition, Thermoid Discovers Real Meaning of 35 Per Cent.—Seeks to Enforce Its Understanding.

Although the New York Royal Rubber Co., which at one time operated on Murray street, New York City, has been adjudicated a bankrupt, its financial troubles are by no means ended, as the Thermoid Rubber Co., of Trenton, N. J., maker, among other things, of the Merit tire, is suing in the New York City Court to recover from Max Weingarten, Henry Durst and Max Durst, the Royal Rubber promoters, on a bill for $1,800, alleging a misunderstanding in the bankruptcy proceedings. When the Royal Rubber company found itself financially involved it formulated a composition whereby the creditors were to get 25 per cent. cash and 10 per cent. on an endorsed note. The Thermoid claim is that when papers of consent were submitted to it the amount named in the document was $630, or 35 per cent. of the $1,800, and that the Thermoid company signed up supposing it was agreeing to accept $630. However, in the bankruptcy proceedings, the Thermoid people allege, they discovered that they had stipulated that $630 was their total bill, and on this basis they were paid 35 per cent. of $630, getting, they claim, only 35 per cent. of 35 per cent. of their real claim. When no satisfactory agreement was reached in the bankruptcy proceedings, the action in City Court was commenced.

Delay in Chassis Delivery Causes Suit.

Delay in delivering to James A. G. Pennington, of Norfolk, Va., a 5-ton Mercedes-Daimler truck chassis which he ordered from the Daimler Import Co., of New York City, November 20, 1911, is named as the basis for an action commenced last week in the New York City Court, wherein the man from Virginia demands $1,932. He alleges that he paid $2,000 on the chassis and that it was to be delivered January 1, 1912, but thus far has failed to appear; also he says he has demanded his money back and it has been refused. Admitting he owes the Daimler people a bill of $68 for supplies, he deducts this amount and asks the court to award him $1,932.

Million Dollar Spring Tire in Spokane.

Out in Spokane, Wash., the good old spring tire has caused sufficient hope to rise in the breasts of several men to enable them to see at least "a million in it." They have incorporated the Fox Spring Tire Co., capitalized at $1,000,000, of which Porter C. Fox, the inventor, is president. The other officers are: D. D. Woolsey, vice-president; W. E. Allen, secretary; Frederick Allgaier, treasurer, and Dallas J. Cogdill, manager.

In addition to the usual combination of steel springs, it is stated that the Fox tire has for a tread "an endless steel chain, composed of a series of short links, said to give resiliency equal to a pneumatic tire," and which also will prevent skidding. The company has opened an office at 415 Sprague avenue, Spokane.

Mercer Discontinues Scapegoat Case.

An order of discontinuance was filed last week in the action brought by the Mercer Automobile Co., of Trenton, N. J., against the Auto Credit Co., of New York City, to determine the possession of a car which, as previously told in Motor World, figured in the escapade of a New York bank president's son. He bought the car, it is claimed, paying for it with a check which his father's bank refused to honor, and the car was subsequently found in the possession of the defendant, from whom it was replevined. The terms of settlement were not made public.

United States Tire Prepares to Move.

The magnificent 20-story white marble structure at Broadway and 58th street, New York, erected by the United States Rubber Co., having been wholly completed, the United States Tire Co., one of its subsidiaries, on or about August 15th will move from its present location across the street. The tire company will occupy the basement and sub-basement as stock rooms, the ground floor for its New York branch and the 15th, 16th and 17th floors as general offices.

J. & B. Succeeds Jacobson-Brandow.

The J. & B. Mfg. Co., of Pittsfield, Mass., which has succeeded the embarrassed Jacobson-Brandow Co., of that city, and which acquired the latter's plant, has added a lamp regulator and a master vibrator to its productions. It also is continuing the manufacture of the Jacobson-Brandow coils.

Oakland Opens New England Branch.

The Oakland Motor Car Co., of Pontiac, Mich., has established a branch in Boston, Mass., which temporarily is located at 591 Boylston street. It is in charge of L. J. Sackett, who has been identified with the automobile industry almost since its inception, latterly with the Cadillac Automobile Co. of Boston.

Mercer Plans Addition to Factory.

Contracts have been let for the construction of an addition to the Mercer Automobile Co.'s plant in Trenton, N. J. The new structure will be of the sawtooth type, 160 x 161 feet. It will be employed for assembling, finishing and painting purposes.

Branch for Lee Tires in St. Louis.

The Lee Tire & Rubber Co., of Conshohocken, Pa., makers of Lee tires, has established a branch in St. Louis at 3567 Linden boulevard. It is in charge of B. O. Leftwich.

TWO TIRES MAKE MUCH TROUBLE

Dispute Between Dayton and Schleicher Over Small Amount Leads to Litigation—Contempt of Court Charged.

When two "airless" tires left the factory of the Dayton Rubber Mfg. Co., in Dayton, O., consigned to the Schleicher Motor Vehicle Co., several months ago, none expected them to be the basis of a lawsuit which would keep the New York city courts busy for months and develop into a second action over the cost of the first suit.

The second section was to have had an airing in the New York City Court yesterday, when the Dayton company made ready to move for an examination of the Schleicher company in supplementary proceedings for contempt of court because, it is claimed, the Schleicher concern has failed to pay a judgment of $25 costs awarded the Dayton company when that concern won out in the original action. The motion, however, was adjourned for a week, and there are reports of a pending settlement. The trouble began after the Schleicher company bought two tires, it subsequently being claimed that they were defective, and suit for a recovery under the guarantee was instituted. The Schleicher company was defeated in the Municipal Court and carried the case to the Appellate Term, where it again lost, and was directed to pay $25 costs, and this amount is the basis of the present litigation.

Burglars Figure in Green's New Answer.

Arthur H. Green, who does business at 1686 Broadway, New York City, as Arthur H. Green & Co., filed an amended answer yesterday in United States District Court for the Southern District of New York in the suit brought against him by the K-W Ignition Co., of Cleveland, O., for the value or return of goods consigned to him about a year ago as New York representative of the concern. The amount asked is $4,367. Green's answer is that some of the goods in question have been sold, some he still has, while others were stolen by burglars. He asks that the complaint be dismissed with costs. The trouble arose over Green's alleged failure to make a weekly accounting and to keep up his payments according to the contract. In his original answer he set up an allegation of defective goods as his principal defense.

Offers New Nameplates for Old Cars.

Awakened to the fact that the name Studebaker has been so greatly subordinated as to be scarcely recognizable on its own productions, the Studebaker Corporation is now counteracting that state of affairs as far as possible. To that end it is offering to all owners of E-M-F "30" and Flanders "20" cars new nameplates, which, instead, bear the name Studebaker.

G. H. Derry has opened a garage in Lamoni, Ia.

Fred Mellor has opened a garage in Liberal, Mo.

W. M. Burton is about to build a garage in Bethany, Mo.

J. B. Roach is about to build a garage in Van Buren, Ark.

John Noller has bought the Wilson Garage in Alma, Kan.

The Automobile Supply Co. has been organized in Miami, Ariz.

Lew Roberson has purchased property and will erect a garage in Ames, Ia.

D. R. McClary of Taft, Cal., has sold his garage on Main street to W. F. Von Breyman.

J. F. Avenell of Fowler, Cal., is about to erect a concrete garage at Merced and 8th streets.

William Sheridan has purchased the O. B. Thomas Garage at Seventh street and Broadway, Concordia, Kan.

R. Shaffer, Jr., of Merced, Cal., is making ready to build a garage on Huffman street, between Main and 15th.

The Methodist Church in Plymouth, Ind., has been sold to Lawrence Bros. who will transform it into a garage.

Patrick Donaldson has established an agency and garage in Moorhead, Minn. He will handle the Warren-Detroit line.

Koehler & Hanson, hardware merchants in Odebolt, Ia., are to build a garage adjoining their present place of business.

E. W. Ruppelt, of Marshalltown, Ia., has purchased the Grout Building from C. E. Alden and will convert it into a garage.

M. L. Harmon of Bloomington, Ind., has bought property on West Kirkwood avenue and will open a garage and salesrooms.

A garage just completed in Corcoran, Cal., by Frank A. Cleveland has been leased by J. B. Peel of Tulare, in the same state.

C. Brooks, owner of the Union Garage in Croville, Cal., has sold out; C. L. Martin, the purchaser, will continue the business.

Edgar Conger and Edward Asplund of Macomb, Ill., have entered the automobile livery business; at present they have but one car.

C. E. McWilliams of Chillicothe, Mo., is about to enter the automobile trade; his business will be styled Chillicothe Auto & Supply Co.

Under the style Carolyn Garage, P. F. Gillett has entered the trade in Turlock, Cal. His location is on East First street near Olive.

Frank D. Cliber and Andrew T. Stone, Jr., have purchased a site on Walnut street Hollidaysburg, Pa., and will erect a garage, 50 x 70 feet.

H. R. Vogel, F. B. McCord and L. H. McMahon, of Carrington, N. D., have formed a co-partnership under the style Bull Dog Garage.

Adam Gilles of Minneapolis, Minn., has been granted permission to erect a one-story brick garage at Powderhorn Park; it will cost $2,500.

The White Front Garage on Park avenue, Niles, O., has changed hands; James Heathman succeeds Swegan & Heathman, the former owners.

The Allen-Ahern Auto Co. of Monticello, Ark., has opened a branch in Warren, in the same state; Joseph McClerkin of Monticello is in charge.

W. W. Overholser of Sibley, Ia., has sold his interest in the Sibley Auto Co. to his partner, Alfred Morton; the latter will continue the business.

G. L. and J. M. Bryson have purchased the Oskaloosa (Ia.) Garage from Robert Ramsey and Howard Taylor; G. L. Bryson will manage the business.

F. G. Withrow and G. E. Finch of Akron, O., have opened a tire repair shop at 15 Library avenue, Grand Rapids, Mich. They have the Republic agency.

Al. Stader, editor of the Ankeny (Ia.) Times, has increased his activities by adding automobiles; he has opened a garage and will handle the Krit car.

F. R. Singlehurst, the owner of two garages in St. Petersburg, Fla., is about to erect a third; this one will be located at Central avenue and 8th street.

Alexander Stewart is erecting a garage, 50 x 135 feet, in Escondido, Cal., on North Lime street, between Grand and Ohio avenues; he will open September 1.

J. S. Waterland and C. A. Andrews of Chico, Cal., have secured permission to build a garage, 124 x 98 feet, at Broadway and 6th street; it will cost $6,000.

Kaukauna Motor Sales Co. is the style to be assumed by a newcomer in Kaukauna, Wis. T. W. McFarlane will be manager and will handle the Marathon car.

Potts Garage is the style under which a new business has opened up in Peoria, Ill., on Margaret street near 4th; the building will accommodate twenty cars.

Farmers Garage is the style of a new business in Plainfield, N. J., on Somerset street, near the North Plainfield line; Wheeler & Titus are the proprietors.

J. P. Shropshire is about to build a garage, 50 x 80 feet, on Broadway, Glendale, Cal. It will be operated under the style Broadway Garage, by Bruce & Waite.

Under the style Kinkler Auto & Supply Co., a new addition to the trade has opened up in Chanute, Kan. Its garage and store is located at 112 North Lincoln street.

J. Witt, J. P. Branck and the Higginsen Co., of San Francisco, Cal., are preparing to erect a two-story garage, 165 x 50 feet, on West Valencia street; it will cost $15,700.

M. H. Perin, of Cincinnati, O., has secured from Samuel Hannaford & Sons, architects, plans for a garage and salesrooms. They will be located on Race street.

J. R. Poole is about to build a one-story garage, 50 x 58 feet, at 12-14 Marshall street, Somerville, Mass. It will be of terra-cotta and will represent an expenditure of $4,000.

Permission has been granted to August Hinn, of Chicago, Ill., to build a one- and two-story garage at 2033-35 West North avenue; it will represent an expenditure of $10,000.

William Whipple of Altamont, N. Y., has purchased a horse livery business in that town and in addition will conduct an automobile livery; his garage is on Prospect Terrace.

Curle & Hayes's barn in Kingsbury, Cal., has been leased to a company which will operate a garage therein; a Mr. Bigelow of Oakland is a principal promoter of the venture.

William Schmidt of College Point, Long Island, N. Y., has secured permission to build a garage, 50 x 100 feet, at 2d and 9th avenues; the plans call for an expenditure of $10,000.

Frederick W. Davis and his sons, Harold C. and Fred L., have entered the trade in Fall River, Mass., under the firm style F. W. Davis & Sons.; they have the Henderson agency.

W. H. Thomson, a San Francisco automobile salesman, has branched out for himself with an agency in Oakland, Cal., "across the bay"; he will handle Alco, Velie and Paige cars.

The Sterling Building and Operating Co. is about to erect a three-story garage, 75 x 90 feet, on Wadsworth avenue, near 176th street, New York City; the cost is estimated at $40,000.

Murray E. Long of Gettysburg, Pa., has purchased the Cresent Automobile Co.'s garage from C. B. Reddig, the former owner; Long has taken possession and will conduct the business.

Mullen & Hunter, machine shop operators in Gilmore City, Ia., have secured plans for a garage to be built adjoining

Digitized by Google

their plant; it will be 50 x 124 feet and of brick construction.

Thomas Vreeland, formerly foreman in several local garages in South Bend, Ind., has opened up for himself at 301-3 East Jefferson boulevard; under the style People's Garage he will operate a taxicab service.

Motor Equipment Co. is the style of a new business which has opened in Oakland, Cal., at Twenty-second street and Broadway, under the management of William S. Bacon; Kelly-Racine tires will be stocked.

A garage, 40 x 60 feet, is about to be erected in La Porte City, Ia. When completed it will be leased to E. H. Mahoney of Cedar Rapids, in the same state, who will, with a partner, establish an automobile business.

Edwin Graff of San Leandro, Cal., is about to build a garage at San Lorenzo avenue and Hepbourn street; J. B. Mills of that town has leased it and will embark in the garage business as soon as the structure is completed.

The Hudson-Phillips Motor Car Co. has succeeded the Phillips Automobile Co. as Hudson distributer in St. Louis, Mo.; John H. Phillips remains the head of the new company, which temporarily is located at 5802 Delmar boulevard.

Charles P. Landman, formerly connected with the Blevins Auto Sales Co., in Toledo, O., is about to incorporate a company for the sale of motor cars in Northern Ohio; among the lines mentioned as a part of the new agency's stock is the Flanders electric.

Edward Bonnheim and Harry Moore have formed the Bonnheim-Moore Motor Car Co. and will handle the new Henderson car in San Francisco, where both are well known to the trade; negotiations are pending for a site on Golden Gate or Van Ness avenue.

W. A. Latham who has been conducting a garage at Court street and Dearborn avenue, Kankakee, Ill., has closed out his business and left for larger fields; he is to secure an automobile agency for several states with Kansas City, Mo., as headquarters.

The Foss-Hughes Co., Pierce-Arrow dealer in Philadelphia, Baltimore, Providence, Wilmington and Newport, is about to invade Washington, D. C., and will locate at 1220 Connecticut avenue. The establishment will be ready for business by September 1.

The Grand Rapids Taxicab Co., under the management of C. A. Knapp, is the style of a new transportation concern in Grand Rapids, Mich. The equipment consists of six Ford cabs; an office will be maintained in connection with that of the Willis Transfer & Baggage Co.

The English Motor Car Co. has been incorporated in Los Angeles, Cal., and has taken over Stevens-Duryea representation in that city. P. A. English is president and Clarence A. English, secretary and general manager. Broc electrics will supplement the Stevens-Duryea line.

P. W. Devendorf, who has been in the automobile trade in Lafargeville, N. Y., for nine years, has increased his interests by assuming control of the Arsenal Street Garage in Watertown, in the same state; associated with him in this latest venture is William Matthews of Lafargeville.

The Lion Motor Sales Co., of 650 Woodward avenue, Detroit, has been reorganized under the style Postal-Fair Motor Co., the title being derived from the names of the principals, H. F. Postal and R. E. Fair; the company will handle the Peerless, Lion and Michigan cars. Postal previously was connected with the Lion company.

White cars hereafter will be sold in Manitoba and Saskatchewan by the White Motor Co., which has been organized for that purpose and which will have headquarters in the Imperial Garage, Osborne place, Winnipeg; E. Chevier and W. E. Roby are the principals in the new concern. The agency has been held for two years by William Richardson of Portage la Prairie.

Arthur Wheeler, formerly assistant manager of the Franklin Automobile Co.'s branch in Syracuse, N. Y., has entered business for himself in that city at 103 Lexington avenue; he takes over the location and Stoddard-Dayton business formerly in the hands of A. M. Zimbrich, of Rochester, and will handle also Haynes cars and Gramm trucks with a line of bicycles and motorcycles.

Richard B. Darre, of 930 St. Nicholas avenue, New York City, formerly of the copartnership Darre and Baramy, which until dissolved in 1911 conducted the Sterling Garage, has filed a petition in bankruptcy, both as an individual and as a member of the firm, which has no assets; liabilities are $9,795 and assets, $265. William Hoffman of 516 West 143d street, who advanced money to the firm, is named as the principal creditor.

Sells Car for Note which is Protested.

Whether it is better to be the owner of a second-hand automobile or the possessor of a note which has gone to protest is a question on which the Stein Tire & Rubber Co., of New York City, has little doubt, and since it parted with the car in exchange for the note, it is now suing the Motor Car Exchange, of New York, in the New York City Court to recover the face of the note, which was for about $700. The car was one which had been used by the tire company for some time, and the bargain was thought satisfactory until later events developed.

Publisher Obtains Two Judgments.

R. H. Donnelley, a publisher, of 227 Fulton street, New York City, and who handles considerable advertising in various directories and guide books, is the creditor in two judgments filed this week in the New York county clerk's office. One, for $38.41, is against the Kosterba Automobile Wagon Mfg. Co., while in the other the debtor is the Garage Service of America, and the amount is $25.01.

Goodyear to Build in Minneapolis.

The Goodyear Tire & Rubber Co., Akron, O., has leased a plot of ground at Hennepin avenue and 12th street, Minneapolis, on which it will erect a building of its own for the occupancy of its branch in that city. The structure will be of brick and concrete, three stories and basement, 57 x 167 feet, and will represent an expenditure of $65,000.

Viso Spark Plug Makers Incorporate.

The Rapp Mfg. Co., of Toledo, O., which manufactures the Viso spark plug, has been incorporated under the laws of that state with $15,000 capital stock. Its officers are as follows: August J. Hummel, president; Wesley S. Rapp, vice-president and sales manager; Chester D. Few, secretary, and Clifford D. Stone, treasurer and general manager.

Paige-Detroit Acquires Engine Plant.

The Paige-Detroit Motor Car Co., of Detroit, has acquired the plant at Leit and Larned streets, in that city, which at one time was occupied by the Gray Motor Co., which recently was released by the United States Motor Co. It will be devoted entirely to the manufacture of Paige-Detroit engines.

Unpaid Tire Bill Brings Judgment.

Judgment for $61.10 was entered in the New York county clerk's office this week against Joseph F. Cox, a Brooklyn garage operator, by the Diamond Rubber Co. of New York. The claim was for tires sold and delivered, and the action was brought in the Municipal Court.

Fisk to Double Capacity of Factory.

To obtain much needed room, the Fisk Rubber Co. has under construction additions to its plant in Chicopee Falls, Mass., which when completed will more than double its capacity. The largest of the new structures is a four-story brick building, 250 x 90 feet.

Willys-Overland Increase Approved.

The increase in the capital stock of the Willys-Overland Co., of Toledo, from $6,000,000 to $15,000,000, was formally approved by the Secretary of State of Ohio last week. The new capital will be used to enlarge the various Willys properties.

Bruce Buys Metal Stamping Plant.

C. Arthur Bruce, treasurer of the Streator Motor Co., of Streator, Ill., has purchased the plant of the Streator Metal Stamping Co. in that city. He paid $30,500 for the property.

Entered as second-class matter at the New York Post Office, November, 1900.

NEW YORK, AUGUST 1, 1912

LESSONS OF THE FARM TRACTOR TRIALS.

Considered from the point of view of the farmer, the farm tractor trials at Winnipeg were interesting chiefly on account of the excellent work done, the low cost of operation and the outnumbering and outclassing of the time-honored steam traction engines. From an engineering point of view, however, the trials are uncommonly interesting because of the somewhat peculiar tendencies in design and construction that were made manifest.

Perhaps the most noticeable peculiarity is the general ignoring of motor car practice in the construction of tractors, and the reversion to types of motors and mechanism now considered almost obsolete, at least for high powers. Instead of multi-cylinder motors of moderate weight and moderate speed, such as reasonably might have been anticipated, the favored practice is to employ huge single or double cylinder motors running at slow speeds, with cylinders that seem enormous as compared with even the largest motor car cylinders. Mixing valves are given preference over float feed carburetters. A single speed, or at most two speeds, with one reverse, are obtained through extremely heavy gears. The ancient swiveling front axle is preferred to knuckle steering, and, in general, simplicity is carried almost to the point of crudity, and strength to the point of excessive weight.

What makes all this particularly interesting is the fact that the machines are built solely with a view to doing certain work and the design is absolutely uninfluenced by other considerations. It is well known that many motor car designers deplore the fact that the unmechanical public's opinion is permitted to influence to a very considerable extent the design of motor cars, and it will be particularly interesting to observe the trend in farm tractors, which doubtless will be designed solely to produce results.

It would appear, however, that the lack of restrictions upon the designer might, with advantage, lead to the adoption of more refinements than were in evidence at the Winnipeg trials. Even if the efficiency of the float feed carburetter is considered dearly bought at the expense of the extra complication, there is no apparent reason, other than economy in manufacturing cost, why there should be an almost total absence of spring suspensions on machines that are built expressly for use over rough ground. A single speed seems insufficient for a machine that has sufficient power to run at its maximum practical speed on a smooth road with its motor turning over very slowly, but which, without adequate gearing, must run its big motor quite fast in order to make a speed of four or five miles an hour.

Still another point that seems worthy of consideration is the ponderous weight of many of the tractors, running in some cases up to 15 tons. The mere moving of such masses over soft ground involves the expenditure of considerable fuel, which means money, and while it may be argued that weight is necessary in order to give traction, it is equally true that traction can be obtained by the use of suitable projections entering the ground and preventing slippage. There are no very serious mechanical difficulties in the way of constructing blades or "paddles" that can be adjusted to extend to any desired depth, and it would seem that the use of less material, but of a higher quality, and the consequent reduction of weight, would result in an economy of power and an all-round efficiency that would justify the extra expense. While the internal combustion tractor has reached a point where it is more economical than a steam engine used for the same purpose, there is opportunity for the application of some of the lessons that have been learned by designers anent efficiency and refinement.

WHY NOT SILENT COMMERCIAL VEHICLES?

It has been said that foreigners visiting New York—or any other large American city, for that matter—often express surprise at the vast amount of unnecessary noise that is permitted in the city streets, making comparisons, of course, with foreign cities where noise that is avoidable is not tolerated. It is not possible, in the nature of things, to prevent noise in business hours, but it is possible to eliminate a good deal of the more unpleasant racket.

For instance, there are many motor vehicles of the commercial classes that raise such a din as to be positive nuisances; the noise is not confined to any one type of mechanism, but is heard issuing from the vitals of all types of cars. That it is not entirely necessary is proven by the fact that other machines of the same general construction are comparatively quiet in operation—in fact, some are almost as silent as the average touring car.

It is of course impracticable to try to build huge trucks and omnibusses that will glide along like the proverbial shadows, but it is entirely practicable to build machines that will not be particularly and emphatically objectionable, and no doubt it will not be long before public opinion, which is content to growl and grumble for a long time before insisting upon remedies, is sufficiently aroused to bring about the results that can and ought to be obtained. It were well did designers forestall such action.

REFUSES TO CONTINUE INJUNCTION

Would be Equivalent to Putting Taxicab Operators Out of Business, Says Court —Why Contract Was Violated.

That there may be some merit in the arguments for the defense in the action recently instituted by the American Taximeter Co. of New York in the Supreme Court for New York county against John Hefferon and John Kavanaugh, operators of the Circle Taxicab Co., of New York City, and the International Taxameter Co. of America, wherein the complainant seeks to enjoin the taxicab company from using any but the American's taximeters, is indicated in a decision handed down on Friday of last week by Justice Gavegan, refusing to continue a temporary injunction against the Circle company while the suit is pending. He points out that if the plaintiff's plea were granted it practically would serve to put Hefferon and Kavanaugh out of business. They have been using several International meters in violation of their contract, and the International company is therefore made a party to the suit on the ground that it had induced the taxicab operators to break the contract they had executed. The main point of the defense is that International taximeters were used because, following a business dispute, the American company refused to supply the taxicab company with meters. Judge Gavegan's decision, which interestingly discusses the oft-discussed subject of such contracts and injunctions, is as follows:

"This motion is to continue pendente lite a temporary injunction restraining the defendants Hefferon and Kavanaugh from using any other taximeter than that owned by the plaintiff, and the defendant International Taxameter Co. from interfering with the plaintiff's rights under the contract. Defendants Hefferon and Kavanaugh are the owners of several taxicabs, and on November 16, 1909, made a contract with plaintiff by the terms of which plaintiff leased to them five taximeters for a period of three years at the monthly rental of $6 each. It is further provided in the lease that defendants will pay for any damage caused to the taximeters by any means other than proper usage; that they will not use the taximeter of any other person, firm or corporation during the term of the lease, and, finally, that if the defendants fail to pay the rent or fail to perform any other act provided for in the contract, then the entire rental for the unexpired term of this contract shall be forthwith payable. Plaintiff claims a violation of that portion of the contract which provides that defendants Hefferon and Kavanaugh shall not use any other taximeter than that owned and leased by the plaintiff.

"Hefferon and Kavanaugh admit that they hired several taximeters from defendant International Taxameter Co., but claim that under the city ordinance requiring them to equip their cabs with taximeters they were compelled to do so by reason of plaintiff's refusal to furnish any more meters until defendants paid for the one damaged. I do not feel warranted in determining on this motion from the facts before me, and so leave for determination at the trial the question as to whether under all the circumstances plaintiff's refusal to furnish defendants Hefferon and Kavanaugh with a new taximeter was justifiable. There seems to be a sharp conflict, therefore, as to whether plaintiff has performed its part of the contract. If it has not it is not entitled to the relief sought, which rests in the sound discretion of the court and should not be granted in a doubtful case.

"The facts before me appear to be analagous to the facts in the case of Ringler Co. v. Mohl (115 App. Div., 549), where an injunction restraining defendant pendente lite from buying and selling upon the premises mentioned in the complaint any beer other than that brewed by plaintiff was reversed on the ground that plaintiff had an adequate remedy at law. The court, in its opinion, at page 551, said: 'In such a case a temporary injunction should not be granted unless it appears that doing the act during the pendency of the action will produce injury to the plaintiff. The effect of this injunction is to compel defendant to purchase the beer that he requires from the plaintiff. The only injury that his not purchasing the beer of the plaintiff will produce will be loss of profits. . . . If the injunction in its present form is allowed to stand, if the plaintiff refuses to sell the defendant's beer, the defendant will have to go out of business. The defendant can purchase no beer except that of the plaintiff, and there is no obligation on the part of the plaintiff to sell the defendant any beer at all.'

"So in the present case, if the affidavits of defendants are to be credited, plaintiff has refused to perform its part of the contract, leaving defendants nothing to do but seek elsewhere for taximeters in order to continue business. The damage which plaintiff will sustain is also more definitely fixed in this case by the terms of the contract itself, and I am unable to say from a reading of the contract with the conflicting affidavits that the consideration of advertising, the loss of which plaintiff claims is a very large element of its damage, was in contemplation of the parties. Moreover, it does not appear that the plaintiff has moved with diligence, for although plaintiff states in its moving papers that defendants commenced to use taximeters other than those supplied by plaintiff some time before this action was begun, it does not appear when such knowledge was brought home to the plaintiff. On the other hand, it does appear affirmatively that about nine months had elapsed since defendants Hefferon and Kavanaugh hired taximeters from defendant International Taxameter Co. of America.

"The case of Standard Fashion Co. v. Siegel-Cooper Co. (157 N. Y., 60), relied on by plaintiff to support its contention, has little or no application on this motion. There the decision was based on a demurrer to the complaint, and the Court of Appeals held, as I understand it, that if any portion of the complaint could be upheld as stating some facts entitling plaintiff to the intervention of a court of equity it should be dismissed. Here, however, the plaintiff is seeking an extraordinary remedy requiring more than mere allegations in a complaint which, if uncontradicted, would warrant the relief. Nor are the defendants Hefferon and Kavanaugh special agents to advertise plaintiff's products, as in the case of Butterick v. Chabot (128 App. Div., 900), but they are merely customers of plaintiff from whom, among others, it made its profits in the usual course of business. Motion denied."

ALLEN STRONG FOR SMALL BORES

Returned American Criticizes Designers for Inattention to Engines of That Type —His Other Views.

According to Harry K. Allen, American designers and manufacturers are, to put it mildly, a couple of steps behind their British cousins in the march of progress that marks the automobile industry. Allen, who is intimately connected with the affairs of the Metallurgique Motor Co., of New York City, which, as its name signifies, handles the well-known make of Belgian car for which the company is named, just has returned from an extensive trip abroad. During the course of his peregrinations he visited all of the principal foreign countries, spending considerable time in England and at the factory of the Metallurgique company in Brussels, and as his trip was principally in the interests of business his opportunity for "looking around" and tracing some of the more marked tendencies to their special lairs was excellent.

Of course, everyone who has visited abroad, or who has had occassion to make critical examination of the most noteworthy differences between the American and foreign cars, has become acquainted as a matter of course with the great differences in bores and strokes — and in bores particularly—which obtains between the foreign productions and Amerisan cars. His remark to the effect that the small bore engine is viewed abroad as the coming type scarcely will occasion surprise, inasmuch as it has been with the development of this type of engine that the foreign designer has been chiefly concerned within the past few years. Similarly, the reason for the active development of the small bore engine which produces a comparatively small amount of power scarcely will require explanation. It is more or less well known that the horsepower tax abroad is excessive and the cost of gasolene has soared to a far greater extent than it has soared in America.

In connection with the cost of gasolene, however, it should be remembered that it is the general practice abroad to measure "petrol" according to the British standard imperial gallon, which contains approximately 1.2 gallons as gauged by the American standards; thus, though the cost of gasolene in England at present is approximately 32 cents, the fuel being sold in sealed 2-gallon cans, the actual cost of gaslene delivered figures out at the rate of approximately 27 cents a gallon, if the quantity in the can is measured according to the United States gallon.

"The foreign designer to-day", said Allen in discussing the matter with the Motor World man, "slowly but surely is eliminating the high power car from his line. There is no longer the demand for cars of, say, 40 to 60 horsepower that there was a few years ago, because it is coming to be generally recognized that it is possible to travel just as far and to climb just as high and to cover roads that are just as bad with an engine of from 10 to 20 horsepower as it is with a very much larger motor. Of course it is not possible to travel quite as fast, although this is not considered, principally for the reason that the speed laws abroad are very much more rigidly enforced than they are in America.

"The use of the small bore engine, of course, has two marked effects on operation in general, the first of them being that fuel consumption is low, and the second that the efficiency of the engines must be relatively high. It seems that the American designer is too willing to overcome difficulties by equipping his cars with a large motor and thereby gaining power at the expense of gasolene consumption and engine efficiency. The foreign designers, on the other hand, appear to have viewed the situation in a very much more logical light. Abroad, because of the high horsepower tax and the high cost of fuel, designers have preferred to take the small bore engine and by careful designing and consistent experiment to develop it to a point where the actual power developed is but very little less than the power developed by the more or less carelessly constructed low-priced American motor which nominally rates at twice its power. The direct result, of course, is that the efficiency of the small engine, both thermal and mechanical, is considerably higher than are the same factors in the American motor. I don't mean to say by this that there are no American motors which approach in efficiency the foreign products. It is true that there are some which are just as efficient, although they are of a larger and heavier type, which fast is coming to be considered obsolete abroad. But I do say without hesitation that the small American motor cannot compare in efficiency or workmanship with the small foreign built engine of the same rating which lists at the same price.

"Why is it that the small foreign motor is superior to the American motor? In the first place, the foreign designer has been designing motors for a greater number of years than has the American designer; consequently his experience is valuable. In the second place, handwork prevails in foreign factories to a very much greater extent than it does in the United States, and though the use of full automatic machinery undoubtedly is excellent practice and results in the standardization of parts and their production in such numbers as naturally reduces first cost to the minium, it is my opinion that handwork is superior to machine work. Also they use better materials abroad. There, metallurgists have been studying metals for a great number of years, whereas in America it is only within comparatively recent years that the study of such things as a science has been developed to a point where it is of any consequence. However, the relatively greater efficiency of the small bore foreign engine may be traced directly to the high horsepower tax and cost of fuel, the combination of which factors practically has forced foreign designers who want power coupled with efficiency and low cost of operation to develop a small bore engine rather than to adopt the slightly larger bore and thereby sacrifice efficiency. All other things aside, the adoption of the larger bore engine would require one of two things: That the purchasers of cars be burdened with greater taxes or that a fight be instituted to alter the laws which govern taxation of motor vehicles. The latter course holds such little hope as to be impracticable.

"Contrary to expectations, and to views which on several occasions have been expressed by others, the Knight type of engine does not appear to be gaining the headway abroad which generally is accredited to it. Quite naturally, most manufacturers of poppet valve engines look at it askance, and as naturally are inclined to sneer at it, though, as far as I could discover, it has been doing satisfactory duty wherever it has been adopted. Nevertheless, there seems to be an impression that though the engine operates well and satisfactorily, it has not been developed to a point of perfection comparable with the poppet valve engine. The concensus of opinion in this respect would seem to be best expressed by a remark credited to L. Renault, of the noted French house of that name: 'It has required more than 10 years of constant study and research to develop the poppet valve engine to its present status, and I don't see how any other type of motor can be developed in a shorter space of time.'

"Engine starting devices abroad have made little or no impression. Foreigners are inclined to view the acetylene type of starter as dangerous and, even when it is considered to be safe, it is not viewed in the light of a real engine starter, inasmuch as it is more or less of a mere priming device, which does not insure infallible starting. However, there are several American makes of acetylene starters on cars, both in England and other European countries, and so far as I can find out, they are giving fairly satisfactory service.

"The electric starter appears to be the coming thing abroad, as it is in America. Quite a number of foreign electric lighting and engine starting devices recently have made their appearance, though there is little attempt as yet to include such devices as stock equipment. This is not surprising, however, in view of the fact that there are few foreign cars which are sold equipped, as the word generally is understood in America. In other words, the foreign buyer purchases his chassis first, and afterward visits his body builder and either selects a body from stock to fit the chassis, or has

Digitized by Google

one built to suit his own peculiar requirements. Incidentally, it is my opinion that there are no American bodies which can compare with those that are built on the other side. Why this should be so I don't know, but I do know that the lines of the foreign bodies are finer and that those manufacturers who specialize in enclosed types can and do produce limousines and landaulet bodies that, even after years of service, retain their pristine loveliness and give no evidence of rattles, such as are common in American bodies."

Size Cutting Follows Price Cutting.

Competition among American tire manufacturers is by no means cold, as was indicated by the alterations in prices made some months ago; but although there is business rivalry, there has not yet arisen the complaint which now emanates from the British Isles. It is said that because of the competiton between tire manufacturers the purchasers of tires are being given less than their money's worth. Deception is practiced, it is said, the favorite scheme of the deceivers being to make tires on which the true size is not stamped, the customer, however, being led to believe that the tire is of full size. The proof of the inferior offering, of course, comes out in service when the undersized equipment falls short of the mileage which might be expected.

The matter is understood to be in the hands of a committee of the Royal Automobile Club, whose object is to investigate the situation and make public its findings. England has suffered from price cutting, and the size cutting is believed to be an effort to keep up with former profits. Size cuts have been, it is said, as much as ten millimeters below the figures stamped on the casing.

Closed Street Bankrupts Garage Man.

Varied reasons are given for bankruptcies, but when a man has the pathway to his garage door effectually blocked he may be said to have a fairly good reason for declaring that he is unable to make ends meet, inasmuch as the rent keeps piling up and there is nothing coming in. Joseph J. O'Connor, who was located opposite Police Headquarters in Bridgeport, Conn., on Fairfield avenue, has filed a petition in bankruptcy, declaring that the closing of the street for repairs has completely destroyed his business. His shop was on the direct road between New York and Boston and business was at one time good, but it fell off as the street deteriorated and traffic was diverted to a better thoroughfare. When the pavement was torn up it was O'Connor's finish, according to himself. His assets and liabilities are, respectively, $500 and $2,598. Other business men on Fairfield avenue have suffered, too, while those on State street, which now gets the travel, are said to have met with a wave unwonted prosperity, much to the chagrin of the Fairfield avenue dealers.

RESILIENT WHEEL WITHOUT SPRINGS

Wheel Within Wheel Principle Applied in Novel Fashion by British Inventor—Torque and Gravity as Cushions.

The idea of a wheel within a wheel always has had a sort of fascination for inventors whose minds run on wheeled vehicles, so to speak, and there even were "push" bicycles built with one wheel within the other in the rear, though the first and last appearances of these machines were identical and simultaneous. Despite the fact, a new application of the principle recently has been made by an Englishman,

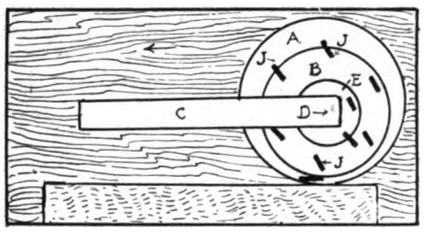

FIG. 1

W. S. Boult, of London, which differs in detail and in operation from the more familiar double wheel arrangements with intervening springs, rubber tires and so on.

The principles involved in the Boult wheel are diagrammatically indicated by the accompanying sketches reproduced from "Autocar." A rough cardboard model is represented, and it illustrates the principle involved, though in a crude way. The letters employed refer to the same parts in both figures. The main or outer wheel A is shod with a tire in the usual way; B is the inner wheel, to the center of which the driving shaft is connected. The propeller

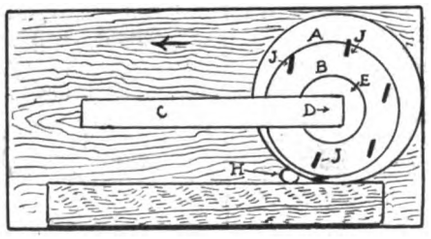

FIG. 2

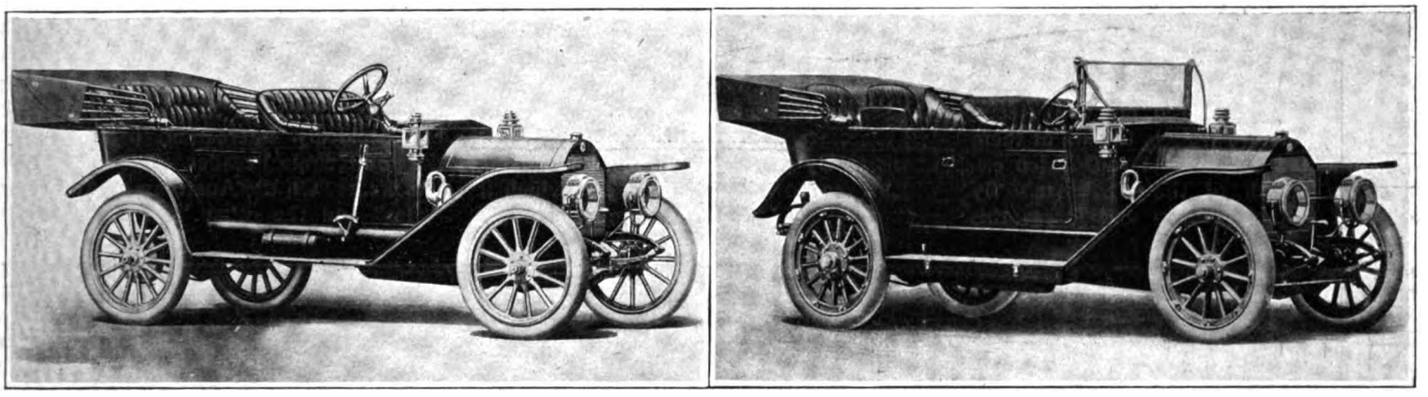
shaft C drives the inner wheel B in the usual way through the bevel gear E; the live axle shaft is represented by D. It will be understood that the wheel is being viewed from the inside, or between the two rear wheels. Connection between the inner and outer wheels is established by means of a set of links, represented by J, so arranged that the inner wheel is free to maintain its position with center below that of the outer wheel, regardless of their simultaneous rotation.

Fig. 1 shows the relative positions assumed by the two parts of the double wheel when the car is running normally on a smooth road; the links J are inclined toward the rear and the inner wheel is a little above and to the rear of the position it would assume were the car stationary, the driving torque having the effect of partially overcoming the weight hanging on the links. Should the outer wheel encounter an obstruction in the road, however, the relative positions would be changed and would be as shown in Fig. 2, in which H represents the obstruction. The inner wheel would swing downward and forward, maintaining the rate of speed of the car, while the outer wheel would be momentarily checked, by mounting the obstruction, after which it would accelerate and assume its normal running position with relation to the inner wheel. The point is that these irregularities of motion, which ordinarily to a greater or less extent are transmitted to the car, are largely confined to the outer wheel, and that the relative movements of the two wheels are cushioned by the fact that the backward movement—or, to be correct, the retardation—of the outer wheel upon meeting an obstruction is cushioned against the torque of the driving shaft, which tends to keep the parts in the position shown in Fig. 1. This torque cushion, as it might be called, takes the place of springs in giving the wheel resiliency. It is claimed that should the outer wheel strike a large obstruction the inner wheel would swing down and then forward and high up and pull the outer wheel over the bump, and the torque cushion effect would prevent violent aftereffects. The resilience of such a wheel would not vary with the load carried, for the increased tractive effort made necessary by the increase of weight carried would balance the forces, and the inner wheel would maintain its position with reference to the outer wheel.

Whether the wheel will come up to the inventor's expectations when put into practical form and tested on the road remains to be seen; the idea is ingenious, however, and the principles involved are of not a little interest, not only because of the apparent possibilities of the design, but because of the wide differences that exist between the Boult wheel and other wheels designed to improve the riding qualities of the motor car.

Milwaukee Sanctions Portable Garage.



The problem which has confronted many of Milwaukee's automobile owners, especially those who dwell in rented houses, of how to avoid the charges imposed by garages for storage has been solved by an ordinance which went into effect last week whereby official sanction and permission is given for the use of the small portable steel garage such as would be suitable for individual service. The measure permitting this form of garage caused considerable discussion, though in support of it there appeared a representative of the garage manufacturers, who marshalled his forces in favor of the proposition and won.

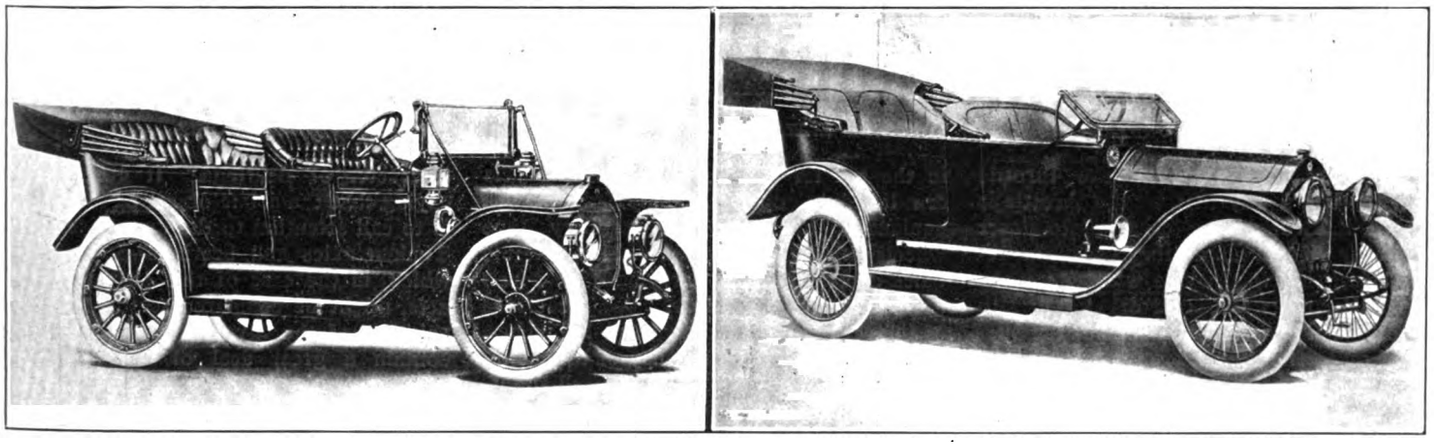
FEW CHANGES IN STODDARD-KNIGHT

New Front Axle and Lighting System Adopted; Wire Wheels Optional—Three Poppet-Valve Models Unaltered.

Permitting very nearly as much latitude for choice as might with reason be expected, the Stoddard-Dayton line, which is produced by the Stoddard-Dayton division of the United States Motor Co. in the factory of the Dayton Motor Car Co., of Dayton, O., will include for the coming season, as it has in the past, no less than three distinct types of motors. Chief among them is the six-cylinder Knight engine, which made its appearance late last year and which in the interim has sustained but one significant alteration in design, the slight change which has been made having been necessitated by the addition of a power-driven air pump. The other two motors which are employed in the other three chassis which go to make up the line are the block motor, which for the past several years has been used and still is used in the 30- and 38-horsepower cars, and the valve-in-the-head motor, which is rated at 48 horsepower and which represents some eight years of development in service in the largest poppet-valve engined car.



STODDARD-DAYTON 30-HORSEPOWER CAR AND THE FIVE-PASSENGER MODEL "38"

The cars themselves, as regards their essential elements, scarcely can be distinguished from their immediate predecessors, except by reason of slight alterations in the body lines whereby the general appearance has been enhanced and the comfort of passengers increased. All of the cars in the line are much improved in these respects, the bodies being roomier and presenting a more finely drawn appearance, which is thoroughly in keeping with the high standard of merit which the manufacturers have set for themselves and maintained. With the exception of the 30-horsepower model, which is the popular-priced car of the line, and is fitted only with touring and compartment roadster bodies, all the chassis regularly are supplied with any of the standard types of bodies, the prices, though including even more equipment than was included last year, remaining the same. The Knight engined model lists at $5,000, the "48" at $2,800, the "38" at $1,850, while the price of the "30" is $1,450.

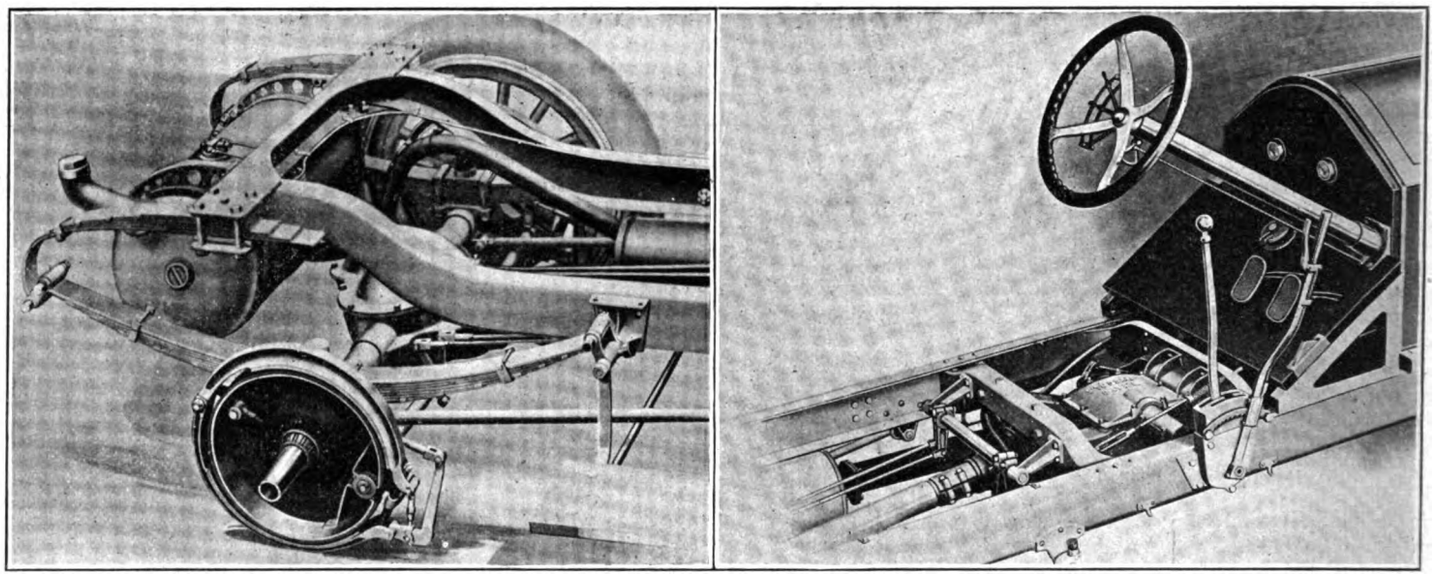
In the Knight-engined model, the manufacturers have continued all of the features which in the first place served to attract attention and warrant the homage of intending purchasers, and in a number of noteworthy instances have supplemented them by others, which place the car on an even higher plane of excellence than in the past. For instance, there is the four-cylinder Kellogg air pump, which has been added and which contributes materially to the comfort of touring in that it permits a quick and easy method of inflating tires. The pump is mounted on an extension of the crankcase and driven by means of the water pump and magneto shaft, which, in turn, is driven from the crankshaft of the engine through the intermediary of a "silent" chain.

Another of the important additions to the already complete equipment which has been made is a complete dynamo electric lighting system. The system is the product of Gray & Davis, and the dynamo which forms its principal unit is mounted on an extension of the change gear housing; the drive in this case also is by means of a "silent" chain, this method having been chosen in preference to the belt drive by reason of its greater positiveness and the decreased liability to troubles caused by grease or oil coming in contact with the driving medium. The remainder of the system includes the usual storage battery and switches, and a complete complement of electric lights.

FOUR-CYLINDER 48-HORSEPOWER STODDARD-DAYTON AND THE KNIGHT "SIX" WITH WIRE WHEELS

The Knight motor itself—and, in fact, all the rest of the car—remains unchanged, with but two exceptions, which embrace the adoption of a new form of I-beam drop-forged front axle, which follows closely the design which has been perpetuated in Columbia cars, and a change in the steering gear, which now is of an improved worm

Digitized by Google



and sector type, in which the bearings all are of the roller type. Other changes of a minor nature include the adoption of a radiator of slightly greater capacity and the use of slightly larger wheel hub bearings.

The cylinders of the motor are cast in sets of threes, the valves, of course, being of the sliding type, which is the distinguishing mark of all Knight motors. The bore and stroke remain unchanged at 4½ inches and 5½ inches, respectively, the rated horsepower being 70. Another of the features of the engine which is almost as much a distinguishing mark as the valve system, is the method of lubrication. Below each connecting rod big end bearing there is a miniature trough, the six of them being mounted on a single rod, which extends the length of the crankcase. By means of suitable cranks and levers this rod is interconnected with the throttle lever in such a way that, as the throttle is opened, the troughs are brought into closer proximity to the connecting rods, the result being that the scoops with which the big end bearings are fitted dip deeper into the oil. This, of course, increases the supply of oil to the bearings, and also splashes a greater quantity on the cylinders and sleeves and auxiliary bearings. The troughs are maintained full to overflowing by means of a gear driven pump within the crankcase, the oil being screened during the process of circulation. Ignition is effected by means of a dual high tension system, the spark plugs being located in the center of the combustion heads.

Carburation is effected in a manner that is no less ingenious than the method employed to ensure efficient lubrication. The carburetter itself is located in the usual position, though the arrangement differs from others in that the air is taken in through a lengthy coreway in the crankcase casting. The result of thus causing the air to take its more or less tortuous passage before finally entering the carburetter is to cause a more homogeneous mixture, due to the fact that the air becomes preheated. Incidentally, much of the wheezing sound which usually emanates from the air intake pipe of carburetters is eliminated.

Of the other essential elements of the car, the large cone clutch with spring inserts and the three-speed selectively operated change gear mechanism are retained without alteration. The drive is by means of the orthodox propeller shaft through a set of bevel gears mounted on a full-floating rear axle. Both sets of brakes are located on the rear wheel hubs as in the past, the service set being internal expanding and the emergency set being external contracting. By way of supplying the demand, which even now is being felt and which it is expected will be felt much more strongly in the not far distant future, wire wheels are listed as optional equipment. Stock equipment includes wood artillery type wheels, which are shod with demountable quick-detachable rims carrying 36 x 5-inch tires both front and rear. The wheelbase of the car remains unchanged at 133 inches, though in line with the policy of the manufacturers bodies have been increased slightly in length in order to provide more legroom for passengers.

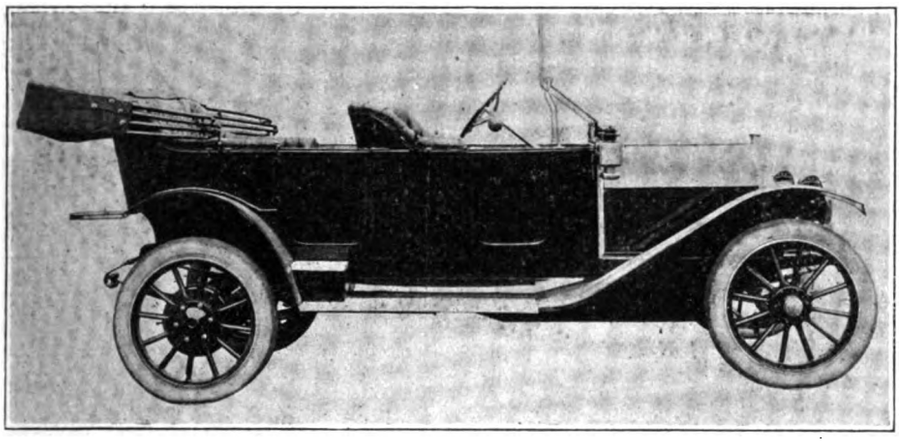
In essentials, the three poppet-valve engined chassis reveal no important changes either in design or construction. In the "48" the cylinders measure 4¾ x 5 inches; in the "38," which differs from the larger model in that a block casting is used, they measure 4⅛ x 5¼; and in the "30," which is of the same L-head construction as the next larger size, they measure 4 x 4½ inches. In each case the clutch is of the leather-faced cone variety, and the gearset provides three speeds forward and reverse, the control being selective by means of a side hand lever. These three cars differ from the Knight-engined model in that they are of the right hand steer variety, whereas in the latter the steering wheel is located at the left with the control levers in the center of the footboard.

REAR CONSTRUCTION AND CONTROL ELEMENTS OF STODDARD-DAYTON POPPET-VALVE MODELS

Two Books Dealing with Bearings.

On first thought it would seem almost impossible to fill even a few pages with matter on the subject of axles and bearings that would be of genuine interest to anyone except engineers and other technicians. That it is entirely possible to do even more, however, has been proved by the fact that the Timken Roller Bearing Co., of Canton, O., has brought out not one, but two, good-sized "Timken Primers" that are decidedly interesting, particularly to the non-technical reader. One of the booklets treats "On the Anatomy of Automobile Axles" and the other "On the Care and Character of Bearings." It goes without saying that the prime object of the primers is to call attention to the fine points of the Timken axles and bearings—a proceeding which, in the case of this concern's products, might be compared to the proverbial painting of the lily—but in addition they contain a great deal of information on axles, bearings and manufacturing processes in general, all told in language so simple as to be distinctly readable and readily comprehended by the veriest ignoramus in things of a mechanical or technical nature.

Franklin Adds a Six-Cylinder Runabout.



To round out its line, the Franklin Automobile Co., of Syracuse, N. Y., is bringing out a two-passenger runabout built on the Franklin "little six" chassis. The runabout will have a folding auxiliary seat in the rear which will accommodate two passengers. In body style it will be of the English type, with cowl dash and high side doors.

SINGLE CHASSIS IN SCHACHT LINE

But It Mounts Two Body Styles—Left-Hand Drive, Long Stroke Motor and Electric Lighting Adopted.

Marking the entry of the Schacht Motor Car Co. of Cincinnati, O., into the ranks of those manufacturers who prefer to center their attention and productive activity upon a single chassis, the Schacht line henceforth will include but two models, a five-passenger touring car and a roadster, and both will be mounted on identical chassis. Incidentally, in contradistinction to all previous Schacht models, the new cars are of the left-hand steer and center-controlled variety, and will be marketed at prices which have been slightly advanced, in order to compensate for the liberal equipment which has been added.

SCHACHT 45-50-HORSEPOWER FIVE-PASSENGER TOURING CAR

As a matter of fact, the equipment which has been added, and which includes such evidences of up-to-date practice as a complete dynamo electric lighting system and a Prest-O-Starter, and the substitution of a new motor of the long-stroke type for the one which has been used in the past, constitutes the most notable alterations which have been made. As a matter of course, minor improvements have been made and corners here and there have been smoothed down, so to speak, though in the main the single chassis which serves for both models differs but little from its immediate predecessor.

In selecting the new motor, the necessity for accessibility and simplicity has not been lost sight of, and to this end the four cylinders are cast in single block with the valves all on the same side, where their enclosure to exclude dust and dirt and ensure the minimum of valve noises is comparatively simple; two light, removable plates serve to house the springs and tappets. The cylinder dimensions are 4¼ inches bore and 5½ inches stroke, which in comparison with the previous dimensions, which were 4½ x 5 inches, lends point to the assertion that the new motor truthfully belongs in the long stroke class; it is rated at 45-50 horsepower. As revealing the efforts which have been made to obtain the acme of accessibility, the exhaust pipe, instead of turning downward at the point where it attaches to cylinders, turns upward, thus permitting valve adjustments or replacements to be made with the greatest facility. Lubrication is effected entirely by force feed, a plunger pump in the crankcase forcing the oil by means of separate leads to all the main bearings and to the spiral timing gears. As an additional refinement, the oil filler plug has been located in proximity to the gauge glass, in order that the "smoke nuisance" may be abated by a judicious filling of the oil reservoir. Ignition is effected by means of a dual high tension system and a cellular radiator in combination with a centrifugal pump and fan ensures that the proper temperature of the motor is maintained at all times.

As was the case in the previous models, a large diameter cone clutch is employed to transmit the power from the engine to the road wheels, the intermediary being a selectively operated three-speed change gear mechanism which is mounted in the waist of the chassis. By way of still further increasing accessibility, the semi-floating rear axle which has been used in the past has been replaced by a full-floating axle in which it is a comparatively simple matter to withdraw the drive axles and the differential mechanism. As heretofore, two sets of brakes are provided, the service brakes, which are pedal operated, being of the external contracting variety, and the emergency brakes being internal expanding. The drums are 14 inches in diameter and afford a total braking surface of 350 square inches, which is more than ample for a medium weight car.

The wheelbase of both models is the same—120 inches—and remains unchanged, as does the spring suspension, which embraces semi-elliptic front and three-quarter elliptic rear members. Demountable rims form one of the items of added equipment; they are shod with 36 x 4-inch tires, both front and rear, in place of the 34 x 4 tires which have been used in the past. The equipment, as already has been mentioned, is complete, and includes, in addition to the Deaco electric lighting system and the Prest-O-Starter, a mohair top with slip cover, folding windshield (the feature of which is the incorporation of adjustable ventilators), speedometer, foot and robe rails, and the usual complement of tools, spares and so forth. In consideration of the better wearing qualities of nickel plate and the growing tendency to eliminate bright brass work, all metal trimmings are plated; the remainder of the paint-work is standard blue-black, though bodies may be finished in any color to suit the requirements of the individual purchaser. The five-passenger touring car, which is styled model "NS," lists at $1,775, and the second model "KL," which is the roadster, lists at $1,650.

Peculiarities of a Foreign Spark Plug.

The problem of preventing short-circuiting in spark plugs through carbon deposits on the insulating cores has been attacked in a novel way by the manufacturers of the Hobson-Pognon plug, a foreign production. Instead of endeavoring to prevent the carbon deposit, the inner end of the porcelain insulation is made so thin that it becomes very hot while the motor is working, with the result that the carbon is burned off and the insulation maintained. It is claimed there always is a clean area of porcelain, no matter how much carbon may be deposited.

Another of the features of this plug is that the sparking points overlap; the overlapping parts are not parallel, however, but at a slight angle, the result being that the spark has a tendency to assume a broad, fan-like form having high efficiency in igniting the mixture.

Imperial Also Takes Up the "Six."

Following the trend of the times, the Imperial Automobile Co., of Jackson, Mich., will include a six-cylinder, seven-passenger car in its 1913 line. The new model will mount a 60-horsepower enclosed valve engine, 4 x 5½ inches, and will have a wheelbase of 134 inches and tires 36 x 4½ inches. Its equipment will include an electric lighting and starting system. The price range of the Imperial line will be $1,250 to $2,500, and in addition to the six-cylinder car and the older four-cylinder models, the line will include a new two-passenger coupe and a five-passenger sedan. Center control and three-point suspension will remain features of all Imperial productions.

Six-Cylinder Stearns-Knight Coming.

Although it has not been wholly a secret, it has become public property that the F. B. Stearns Co., of Cleveland, will add a six-cylinder Stearns-Knight model to its 1913 line. The newcomer, however, will not be ready for delivery until about October 1st.

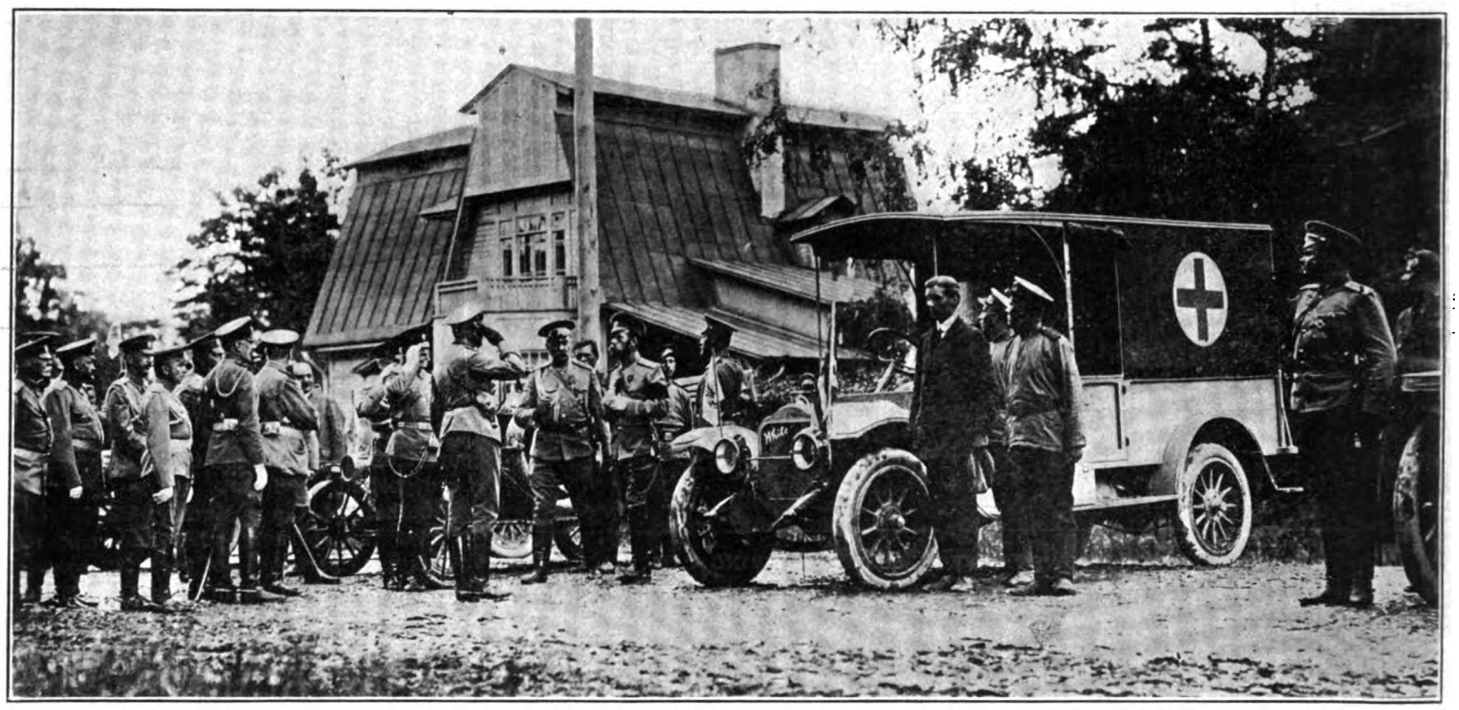
RUSSIA'S TEST OF ARMY TRUCKS

American Vehicles More Than Hold Their Own in Competition With Europe's Best—Trial Lasted 17 Days.

In its effort to find the truck, or trucks, best adapted to the use of its army, for which an order aggregating 2,000 vehicles probably will be placed, the experiments conducted by the Russian government were of a most exhaustive character. They took the form of a 17-days reliability contest of an unusually difficult nature, which was in charge of General Dobrecshin. Forty-five vehicles presented themselves for the trial, which started from St. Petersburg on June 6th.

The flower of European motor vehicle production was represented by Mercedes, Benz, Napier, Saurer, Adler, Clement, Lancia, Berliet, Charron, Laurin, Buire, Vauxhall, and others. The American "White Squadron" was made up of two five-passenger 20 horsepower touring cars, two 30 horsepower field ambulances, using the regular White three-quarter ton capacity truck chassis, and one one-and-one-half ton capacity 30 horsepower truck, fitted with tank body for carrying the fuel supply for the tour.



The route covered started at St. Petersburg, circled around through Moscow, and then returned over a different course to the Russian capital, the entire distance traversed amounting to about 1,960 English miles. The road conditions were indescribable. In many places there were no roads at all, the course being across sand hills, over fields and ploughed ground, and through forest trails. The best idea of the traveling conditions can be gained from the fact that it was necessary to precede the tour by a detachment of army bridge-builders in order to make it possible for the cars to get through at all.

The trials ended in St. Petersburg on June 23rd, after 17 days of the hardest service. The last three days' run was made at high speed over hard, rough roads, and was extremely exacting. Thirty-five cars finished the trip, among which were the five White contestants, with the record for a lower consumption of gasolene and oil than any of the European cars.

All five Whites went through the entire trip without mechanical trouble of any description, and created no little admiration among the Russian officials who supervised the trials. At the close of the run, all of the surviving contestants were assembled at Peterhoff, where they were personally inspected by the Czar of Russia, the Minister of War, and the high officials of the Russian army. The "White Squadron," on account of its fine performance, received a share of the Emperor's attention.

After the imperial inspection, all of the contesting cars were completely dismantled and every part was subjected to careful scrutiny for wear and deterioration. The commission of experts who conducted this examination reported that every one of the five White cars and trucks was in perfect condition. This report was followed by the report of the army officials that the White cars were suitable in every respect for the requirements of the Russian army service, and recommended that the entire five cars be purchased by the War Department. The next day the victorious "White Squadron" became the property of the Government of Russia.

The result of the trials and the subsequent action of the Russian Government is naturally very gratifying to the White Co., whose cars won out in the severe test against representative cars of Europe. While practically all the European cars were handled by factory experts, the White vehicles were taken care of by men from the London office of the White Co. and its agency in St. Petersburg, no factory representatives being present.

CZAR OF RUSSIA APPEARS ON THE SCENE TO CAST AN EYE ON THE WHITE VEHICLES

Hammers as Substitute for Wrench.

It sometimes happens that the large wrench necessary to remove a valve cap or hub cap is not available, notwithstanding the urgent necessity for unscrewing the part. In such an emergency, the work often can be done by holding one hammer or some other heavy piece of metal against one of the faces formed for the wrench and striking the diametrically opposite face with another hammer. The weight should be held near the corner that will be leading when unscrewing, and the hammer applied near the leading angle on the opposite facet. If the cap or nut is tight it will start very much more easily in this way than if the hammer alone is used. Obviously, if the hammer is not handled carefully, so that its face strikes flat on the face of the cap, more or less marring of the surface will occur. If the surface is a finished one it should be protected by a piece of sheet brass or copper or even hardwood. This method of removal as an emergency measure should should be resorted to with care.

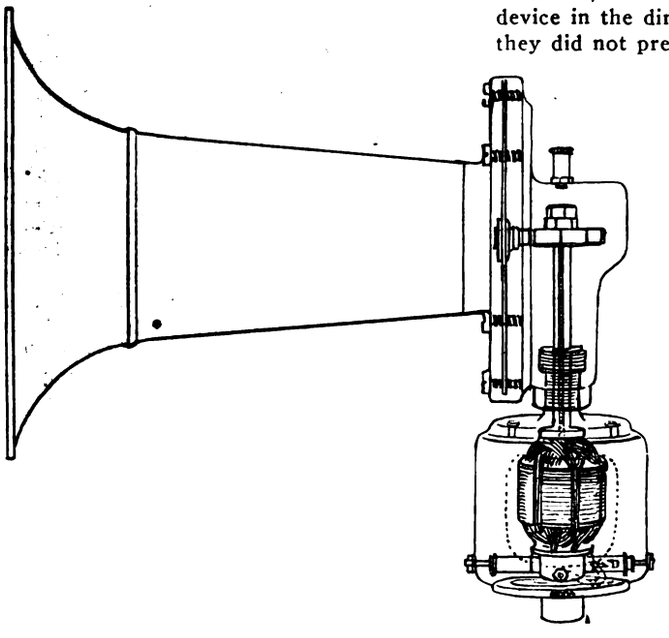
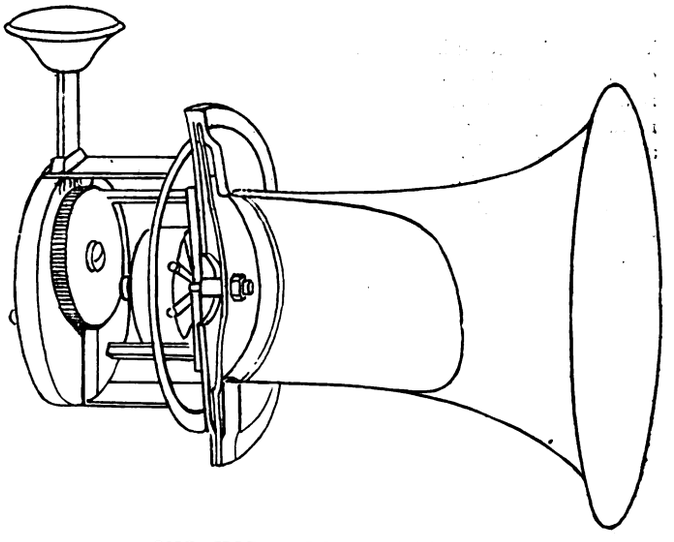
UNCOVERING THE "NOISE" IN THE MECHANICAL HORN

Ingenuity and Variety of Design Disclosed by Baring Internals of Modern Signaling Devices Built Around Drumhead Principle—The Three Types and the Differences That Distinguish Them One From the Other—Diaphragms That Vibrate 30,000 Times a Minute.



During the first few years of motor car development, when an automobile "announced" its approach by noises that were audible long before the vehicle hove in sight, little or nothing was heard of the necessity of equipping motor vehicles with a really effective warning signal. Probably their designers were too absorbed in the task of eliminating the noises that vied with those which any signaling device could produce.

Necessity, however, is the mother of invention, and as careful designing and better constructional methods and facilities gradually eliminated noise center after noise center, and study and care reduced the sounds which it seemed impossible to silence, cars of the self-announcing variety gradually disappeared, and something in the way of a warning producer became more or less a necessity. Bells and gongs, which have reigned supreme as warning signals in the cycling world never found much favor with those who had to do with motor cars; probably for the reason that the tone of such devices was not sufficiently distinctive from the sharp metallic clinks and clanks which accompanied the operation of early automobile motors to be easily recognizable as a warning signal. At any rate, the bulb horn, with its brass or bronze reed set in vibratory motion by the action of a column of air forced by the action of a rubber bulb and which set up a distinctive grunt which neither was musical nor entirely displeasing to the sense of hearing, found instant favor, and became the standard warning device.



The inherent effects of the bulb horn—the inability of the bulb to "stand up" for any considerable period, the disposition of the reed to be affected by water and dust, the possibilities, in no wise remote, of the connecting tube developing a leak, the failure to project the sound to considerable distances, and a general inaudibility of the device in the din of street traffic—although they did not prevent nor limit the development and application of the bulb horn, they did lead to the production of other warning apparatus of various types which are more rugged and, at the same time, more efficient as sound producers. It is not at all unlikely that, had four and six cylinder motors attained the ascendency at an earlier period or had efficient storage batteries been used instead of dry batteries for ignition services, either the exhaust horn or the electric type of signaling device quickly would have found favor. With all its defects, however, the older type of signaling device still persists, and not a few of its staying qualities are derived by virtue of the adaptability of the horn to meet any and all conditions—that is, simply by varying the speed with which the bulb is collapsed, the volume of sound from the horn can be controlled and fitted to the needs or conditions. This also is true of the exhaust horn, and of the electric devices in some cases, but as a rule with the electric horn the volume and tone of the device cannot be varied.

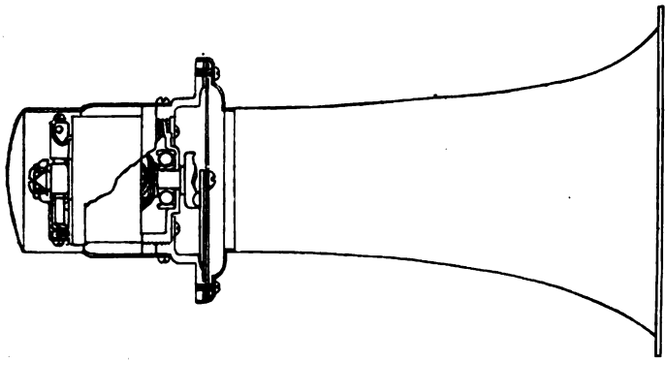
Signaling devices other than bulb horns, which for want of a better term may be styled mechanical signaling devices, since in each of them either gear wheels, cranks or levers or some other well known mechanical devices are used either for the actual production of the sound or for its control, can be classified under three general heads: those which are operated by electricity, those which are manually operated, and those which are operated by the exhaust of the motor. Devices of the first class are by far the most numerous.

Although those who have to do with motor cars can, in nine out of ten cases, differentiate between the different classes of signaling appliances by either the quantity or the quality of sound issuing from the devices, few are sufficiently familiar with the works of the mechanical devices to be able to say really just what produces the sound. Unlike the drum which, when the head was punctured by the curious small boy who desired to see where the noise originated, revealed nothing but emptiness, to the consternation of the lad, the mechanical horn reveals not only not a few component parts which have to do with the production of the sound, but more ingenuity and variety in their design and arrangement than is generally supposed is the case.

KLAXON RIGHT ANGLED CONSTRUCTION

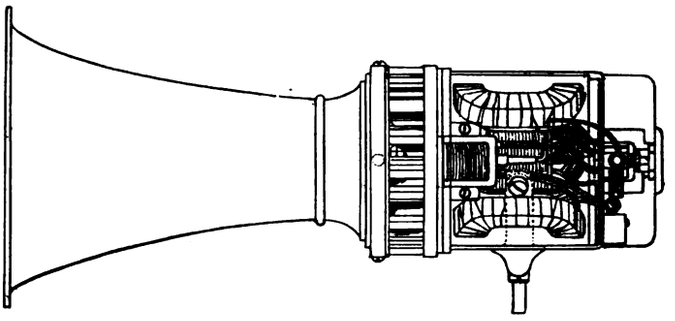
LONG HORN "ROLLER-TOOTH" CAM

Digitized by Google



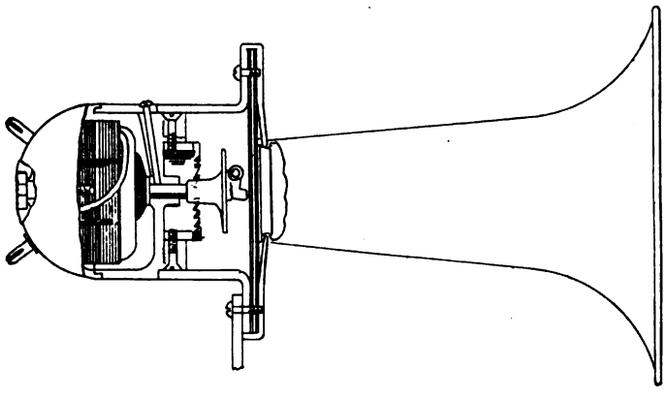
With the electric horn, for example, the noise generally is produced by the more or less rapid vibration of a metallic diaphragm placed across the mouth of the megaphone or projector. Practice with regard to the operating mechanism which imparts the desired motion to the diaphragm, however, differs widely. There are those who, like the makers of the Klaxon and Newtone, install a small motor to impart the desired movement and sound, while others—among them the producers of such horns as the Tuto and Mesco—pin their faith to a series of electro-magnets and an armature which is attracted by current in the magnets and retracted by the action of a spring during alternate intervals.

With the motor driven type of diaphragm horn, the rotary motion of the armature shaft is converted into reciprocating or vibratory motion through the intermediary of a cam wheel attached to the revolving shaft, the teeth of which act upon a shoe or anvil positioned either directly on the diaphragm or on a lever which comes in contact with the diaphragm, according to the ideas of the designer.

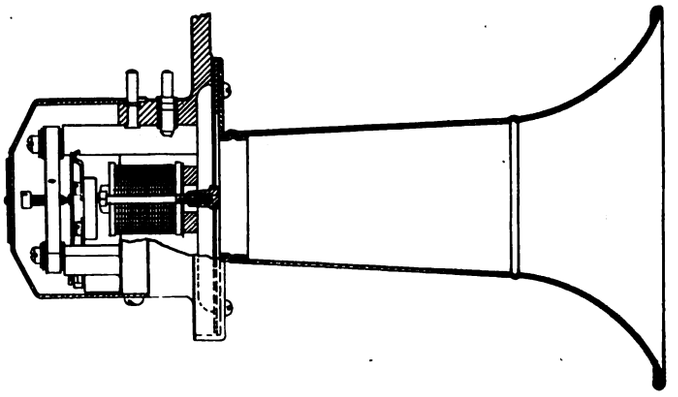


The Klaxon, produced by the Lovell-McConnell Mfg. Co., Newark, N. J., and which set the fashion for mechanical horns, is distinctive from other electric signaling devices of the same type in that the motor shaft is parallel with the plane of the diaphragm, whereas in all others the shaft is normal to the diaphragm. The diaphragm is a flat piece of heat-treated vanadium steel, 5½ inches in diameter, supported between cork gaskets in a housing formed by the base of the projector and the casing which houses the cam or ratchet wheel. The motor, which is provided with laminated field pieces and laminated drum wound armature, is housed in a separate casing below the rear portion of the projector. Brushes are made of tightly compressed copper netting and the interstices filled with a suitable lubricant to reduce friction and yet not cause sparking, as would be the case were the brushes lubricated with oil. The armature shaft revolves on ball bearings at a speed of 3,000 revolutions a minute, so that the anvil on the diaphragm is struck 30,000 times a minute, there being ten teeth cut on the periphery of the cam wheel. Freedom from wear of the cam wheel and the anvil, which are the parts which work under the most trying conditions, is insured not only by the quality of steel which enters into the construction but also by the ample lubricating facilities provided by the oil hole, which is positioned in the top of the cam wheel casing. The terminals of the Klaxon are carried through to the outside of the motor casing, so that the cables can be attached and detached without the removal of covers.

Radically different features appear in the design of the Typhoon, made by the Typhoon Signal Co., Chicago. In common with the Klaxon, separate casings house the motor and the ratchet wheel, which, however, is stationary and is fastened to the plate which separates the two casings. The armature shaft, which is carried through the separating wall through a plain bearing, carries a disk or face plate provided with two lugs in line, to which is pivoted a dog. The dog is in the shape of a bell crank and the pivot passes through the angle so that the longer leg of the dog comes in contact with the teeth of the ratchet wheel, while the shorter leg, which is slightly weighted on the end so that a head is formed, is free to "tap" the vanadium steel diaphragm. For each revolution of the armature shaft there are 24 taps, so that when the motor is revolving at full swing—3,000 revolutions a minute—a tone neither distinctly musical nor yet so harsh and metallic as to be entirely displeasing is emitted by the rapidly vibrating diaphragm. Owing to the fact that the diaphragm is not weakened by being pierced, as is the case when the anvil is placed on the diaphragm, it is claimed that the latter is not so liable to crack, and this freedom from breakage, too, is made more certain by the small distance through which the center of the diaphragm vibrates. The motor of the Typhoon is provided with laminated field pieces and armature, and is snugly enclosed in a protecting housing. Lubrication is provided for by means of ducts which carry the oil to the plain bearings of the armature shaft and which can be closed by screw plugs.



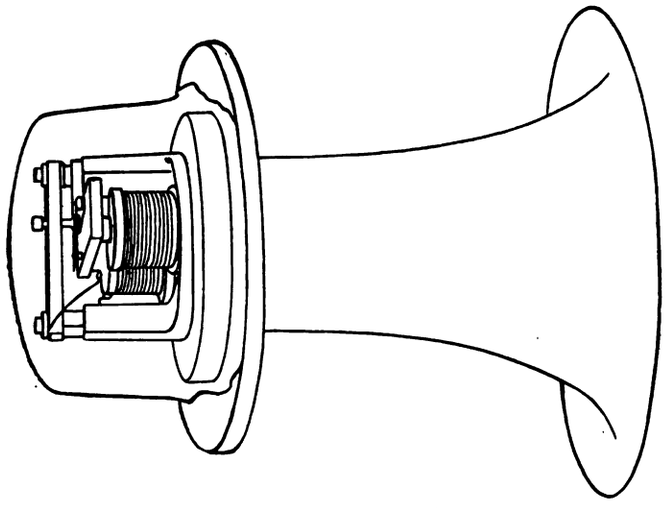
But six teeth are provided on the cam wheel of the Newtone horn, which is made in Brooklyn, N. Y., by the Automobile Sup-



NEWTONE MOTOR-DRIVEN DIAPHRAGM HORN

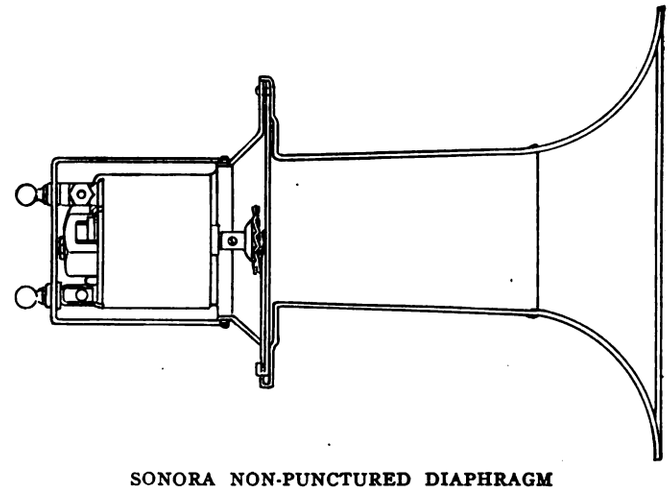
OPERATING MECHANISM OF THE SIRENO

TYPHOON STATIONARY CAM MECHANISM



INTERNAL ARRANGEMENT OF THE TUTO

Digitized by Google



ply Manufacturing Co., and the drops between the teeth are shallow. The angles on the face of the cam are very much modified, which, in conjunction with the shallowness of the drops, makes for easy and consequently quick starting of the motor, with the result that the maximum noise can be produced in a very short interval. The limited height of the teeth, however, does not interfere in the least with the magnitude of the vibration of the diaphragm, for this is increased over the height of the teeth through the agency of a small lever to which the anvil is attached and which serves to transmit the motion to the diaphragm. Freedom of movement of the armature shaft is insured by the Hess-Bright ball bearings on which it is mounted, while the self-lubricating brushes also tend to eliminate friction. The motor, which is built after the best modern practice, with laminated field pieces and armature, is entirely self-contained and can be removed from the rest of the apparatus simply by loosening a lock nut and unscrewing the motor from the rear half of the casing which houses the diaphragm. In the same manner adjustment for wear either of the cam wheel or of the anvil can be made, save that in this case the motor is screwed further into the casing, which brings the cam wheel closer to the anvil. The method of conducting the current from the terminals, which are positioned outside of the case close to the diaphragm, is unique. From the inside of the terminals two brass brushes lead to two concentric brass rings which are mounted on a fibre plate, which in turn is mounted on the front of the motor casing. The rings are connected with the leads which conduct the current through the motor. When the motor casing is revolved the brushes rub on the surface of the conducting rings, so that contact is effected, no matter what the position of the motor happens to be. The horn can be taken apart without the risk of breaking connecting wires through this arrangement. Like the Klaxon, Newtone practice embraces the use of a 5½-inch vanadium steel diaphragm which is held between cork gaskets.

Like the Newtone, the Sonora employs a lever to transmit motion to the diaphragm and to amplify the distance through which the diaphragm vibrates over the depth of the teeth in the cam wheel, but the arrangement differs slightly from Newtone practice in that the lever is not fastened to the diaphragm, but taps it in a manner similar to that of the dog in the Typhoon signal. Owing to the comparatively light parts which are moved by the motor, the latter is small, consuming, it is claimed, but 2¾ amperes. The cam wheel, which is made of pressed sheet metal and consequently is very light, is provided with 10 teeth which impart 30,000 blows to the diaphragm every minute. A self-contained motor with plain bearings, which is amply protected from dust by a casing, is one of the features of the design. The Sonora is made by the Sonora Motor Horn Co., of New York City.

Radically different from either of the motor driven horns already described is the Sireno, product of the Sireno Co., New York City, and which, as its name implies, embraces the use of a siren to produce the warning signal. The instrument, however, does not produce a sound which fluctuates in pitch within wide limits as the speed of rotation of the rotor increases and decreases, that is, the fluctuations occupy such a short interval of time that they are not noticeable. The rotor of the horn is made of cast aluminum, carefully machined and mounted directly on the armature shaft. The light weight, which means small inertia to retard the starting speed of the device, and the reduced friction of the shaft bearings owing to the use of ball bearings, enable the motor to attain its highest speed within a very few seconds, while the action of a magnetic brake, which is brought to bear against the rotor directly the current is broken at the switch, retards the motion of the shaft and appurtenances in an equally short space of time. The motor is of the drum wound type with laminated armature and cast steel field pieces, and is housed in a tight casing behind the rotor. The employment of ball bearings and the entire absence of other frictional surfaces save the brushes, which are self lubricating, preclude the necessity of oiling the device. The rotor, which, in conjunction with a series of slots that are cut in the circumference of that part of the housing which serves to cover the device, produces the noise, is nothing more nor less than a centrifugal fan, that is, a fan which, owing to the speed with which it is rotated, throws the air, which is admitted to the base of several radial passages at the hub of the wheel, out at the periphery, where the passages terminate. The air thus thrown off passes through the slots in the housing, and the more or less weird sound is produced, the tone and the pitch varying according to the number of "puffs" which are created during a given interval of time. With the Sireno the air is admitted to the passages at the hub of the rotor through the intermediary of the projector or bell of the horn.

HIPWELL AUTOPHONE CONSTRUCTION

SONORA NON-PUNCTURED DIAPHRAGM

Of the electric diaphragm horns in which the "buzzer" action is incorporated, probably none is better known than the Tuto, made by the Dean Electric Co., Elyria, Ohio. The name is not idly chosen and is intended to convey the meaning that two separate and distinct sounds, or in reality two different degrees or volumes of the same sound can be produced at the will of the operator. The internal mechanism of the Tuto, analyzed, reveals nothing more complicated than the action which is enclosed within an ordinary trembler bell. An armature made of soft iron, so that it will not become permanently magnetized, is placed a short distance from the pole pieces of a couple of electro magnets, and is held "hinged" in this position by means of a piece of spring steel. Naturally any current which passes through the magnets causes the latter to attract the armature against the action of the spring. When the flow of current is interrupted the

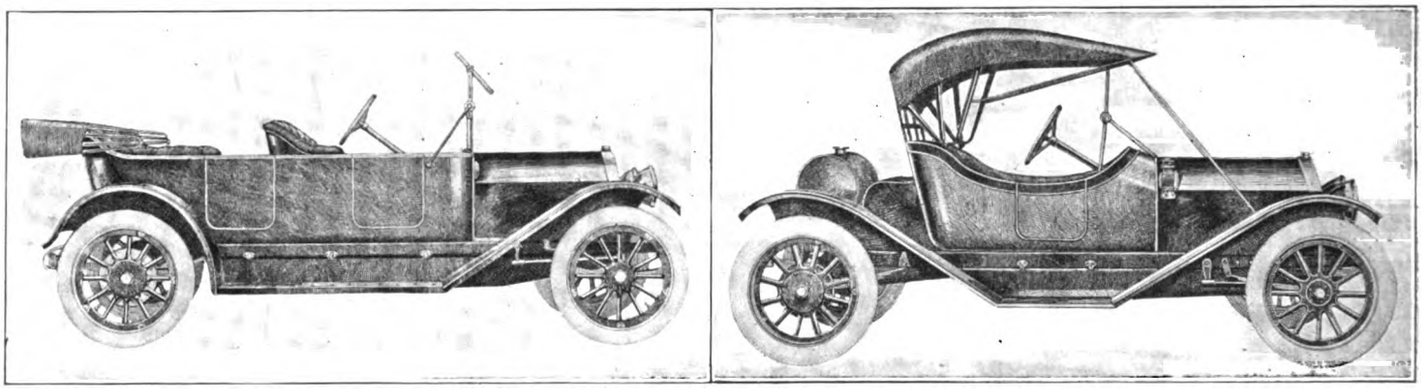
OFFERS MORE CAR FOR LESS MONEY

Great Western Finds Ways of Attaining that End—New Model Marked by More Power and Full Equipment.

Despite the fact that the revised edition of the Great Western car, which is designed to take the place of the cars that have been marketed under the same name in the past and to continue the renown of the Great Western Automobile Co., of Peru, Ind., is a bigger car throughout than ever before with a brand new motor of greater horsepower, and a more completely equipped car, its price has been fixed at $1,585, which represents a reduction of just $265. The reduction, it is explained, is made possible by reason of a material increase in output which will be made, though it should be apparent to the average individual that though a saving has been effected in this way and also because of greater shop efficiency a considerable portion of the abbreviated "overhead" has been turned right back into the cars in the form of extra equipment, more careful workmanship and more impressive finish.



As heretofore, the line is built upon a single chassis and includes four- and five-passenger touring bodies, a roadster and a four-passenger fully enclosed car that not inaptly has been styled a "Sedan." In keeping with the more luxurious character and fittings of the Sedan, its price has been set at $2,250. As already has been mentioned, the equipment is complete in the real meaning of the word, and includes a silk-mohair top with Fairfield rubber dust cover, rain-vision ventilating windshield, Stewart speedometer, Solar electric head, side and tail lamps, Typhoon electric signal, gasolene gauge, demountable rims with an extra rim, tire irons, tool box, tools and spares.

The most important change which has been made concerns the motor, of course. Following out the policy of the manufacturers, who always have inclined to the use of long stroke engines, the new power plant has its four cylinders cast separately, the bore and stroke being 4¼ inches and 5½ inches, respectively. The valves are large and their position all on the same side facilitates the use of a single light dust-proof cover, which renders the valve action as quiet as it is possible to make it. One of the excellent features of the engine which has as its laudable purpose the prevention of carbon deposits collecting to cause trouble, is that the piston heads are convex. Incidentally, the construction materially strengthens the parts which are made as light as possible in order to reduce the strain caused by high rates of reciprocation. Another new feature is the location of an oil groove in the pistons below the wrist pin. The groove is drilled at several points to permit excess oil to drain back into the crank chamber and thus prevent smoking.

Lubrication is effected mainly by splash with auxiliary oil leads to the main bearings and to the spiral timing gears which are contained within the crankcase. The oil is maintained in constant circulation by means of a positively driven plunger pump of adequate capacity. Cooling is by pump circulated water and the mixture is fired by a high tension Remy magneto. Power is transmitted from the engine to the rear wheels through the intermediary of a large, leather-faced cone clutch and a three-speed selectively operated change gear mechanism in which the through shaft and the lay shaft are located side by side. Thus, all the gears receive the same lubrication and are equally accessible for inspection when the gear case cover is removed. The differential is contained in a pressed steel housing which is equipped with an extra large inspection plate and the rear axle is of the full-floating type.

By way of providing "soft" riding, the springs have been increased slightly in length, the front semi-elliptic members measuring 40 inches in length and the rear members, which are of the three-quarter elliptical variety, measuring 47 inches in length. For the same reason and also to increase the desirable quality which best is explained by the term "roadability," the wheelbase has been lengthened to 118 inches. Despite the longer wheelbase, however, the shape of the frame and the arrangement of the steering connections is such that the car can be turned quite easily in a fairly narrow street.

Great Western bodies are a combination of steel and wood, and great pride is taken in the fact that in the finishing process no less than 18 operations are necessary. Giving evidence of the roominess of the seats, the rear compartment in the five-passenger touring car measures 49 inches in width. Throughout the cars, attention has been centered on efforts to increase the comfort of passengers, one little instance being the location of a good sized pocket for goggles and memoranda between the two front seats. Smoothness of appearance also has claimed attention, and to this end door hinges and latches have been removed to the comparative obscurity of the inside and there are no outside projections or protuberances to be knocked and deformed by passing vehicles.

GREAT WESTERN "40" TOURING CAR AND ROADSTER—BOTH OF WHICH LIST AT $1,585

To Make Blue Prints Black and White.

Although it seldom becomes necessary to make additional prints from a blue print, it is possible to do so provided the original print first is converted into one in which the lines are black and the background white. The operation to change the color is neither difficult nor does it require a great amount of time. It is merely necessary that the print be immersed in a solution formed of ¼ ounce of ordinary borax dissolved in 6 ounces of cold water. When the print has blackened, it should be removed and washed thoroughly and placed in a solution composed of ¼ ounce of gallic acid, ¼ ounce of tannic acid and 8 ounces of cold water. This will intensify the color and make the print permanent.

Low Tank That May Cauce Backfiring.

If the motor shows a tendency to fire back through the carburetter when ascending a grade, it is well to make sure that the gasolene tank is high enough properly to supply the carburetter before looking elsewhere for the trouble. If the tank is only very slightly too low, the back firing will occur only on severe grades.

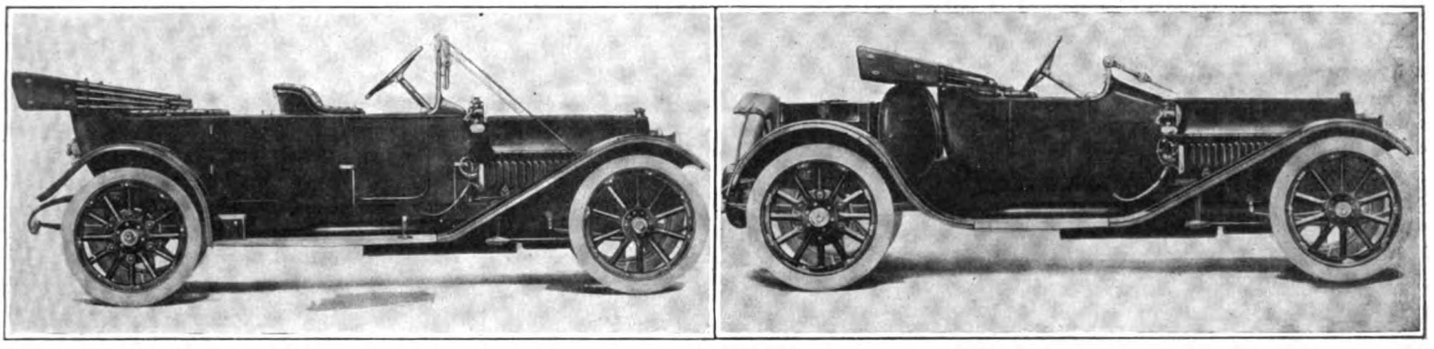
CHALMERS CARS IN 14 BODY STYLES

Standardization That Has Affected "Six's" Price—Three Chassis and a New Air Starting System.

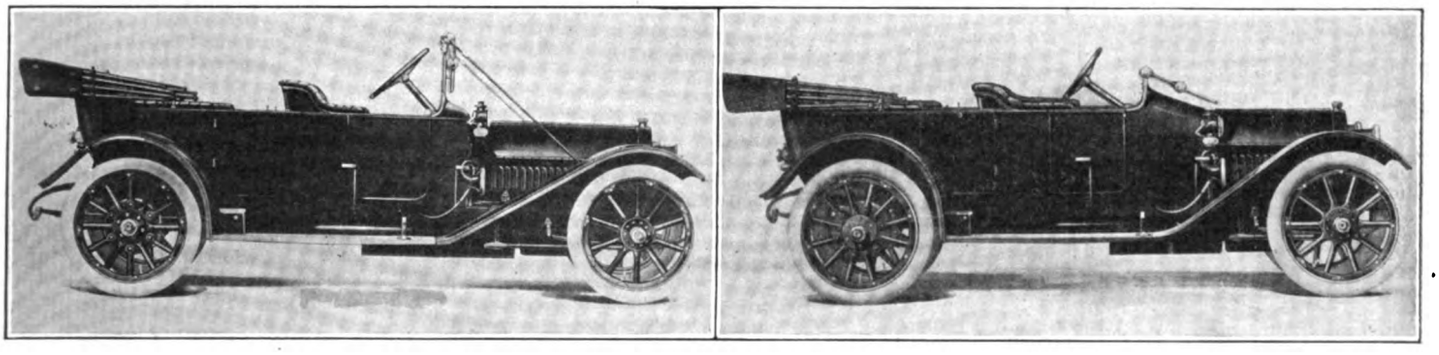
Although the merits of standardization have been extolled and its praises have been sung, it is seldom that more concrete evidence of its advantages is given than is afforded by the action of the Chalmers Motor Co. of Detroit, Mich., which, by reason of the adoption of such advanced practices, has found it possible to reduce the list price of its six-cylinder model from $3,250 to $2,300. In explanation of the $950 cut in price that has been made, it is pointed out that, though the standardization of many of the parts which go to make up both the "six" and the four-cylinder model which is styled the "36" has had a very material effect on the cost of production, no inconsiderable portion of the reduction can be traced directly to the increased manufacturing facilities which in the past year have been effected.

Despite the very noticeable reduction in price, however, the car itself is just as big as ever; in fact, it scarcely has been changed at all, except that it has been made even more attractive by careful refinement and the addition of a complete dynamo electric lighting system to the already well-filled equipment list. The other cars in the line—the "30" and the "36," both of which are four-cylinder models—have suffered practically no alteration, the "30" being continued in the same form in which it was introduced some five years ago and at the same price, namely, $1,500; the "36" still lists at $1,850, at which price it made its initial appearance last year, just prior to the launching of the "six."



Although it is not always possible to accept the statement "practically no alterations have been made" in its literal sense, it is quite possible to do so in the case of the Chalmers line. Such changes in mechanical construction as have been made can be counted on the fingers of one hand. By far the most noticeable changes are apparent in the construction and appointment of the bodies, which under the hands of skilled designers have been developed to the point where the intending purchaser scarcely can find anything to desire either from an esthetic point of view or from the more material point of view of the passenger. The cowls of all the models have been made deeper and serve to mount the usual dash accouterments, such as the oil and air pressure gauges, the speedometer and the ignition and lighting switches. The upholstery has been increased in depth from 10 to 11 inches, and by reason of its luxurious character and the absence of the usual tufting, which has been replaced by softly folded leather, has been styled "Turkish cushioning."

The bodies themselves are of entirely new design, in which pains have been taken to ensure harmoniousness between the lines of the doors and sides and the engine hood and cowl. To this end, the mouldings have been made exceedingly fine and all external protuberances have been relegated to less conspicuous places inside. One of the distinctive features of the design, which is carried out in substantially the same manner in all the models, is the absence of the usual filler-board between the windshield and cowl. Instead of being mounted on a board, the windshield is formed to fit the cowl, to which it is attached directly.



Regarding the mechanical construction of the three cars in the line, the only alteration which can be viewed in the light of a real change from previous practice concerns the driving axles. The axles themselves all are of the full-floating type, and in place of the crab drive to the wheels, which has been used in the past, a flange which fastens to the rear wheels by means of six bolts is used. The reason for the change, it is explained, is to eliminate the possibility of lost motion at this point.

Such other mechanical changes as have been made really are more in the nature of additions to equipment. Thus, for instance, though the distinctive Chalmers air engine starting is retained, the method of obtaining the necessary air pressure in the reservoir has been altered and now is effected by means of a four-cylinder Kellogg air compressor, which is connected to the pump shaft of the engine through the intermediary of a "silent" chain. Under the old regime, pressure was obtained by means of a check-valve inserted in one of the engine cylinders. The addition of the air pump makes possible the inflation of tires with pure air instead of with compressed burned gas, as was the case last year.

The other noteworthy addition to equip-

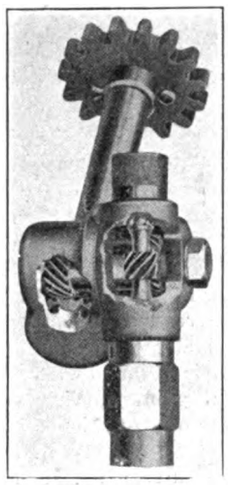
CHALMERS "SIX," WHICH LISTS AT $2,300 IN TOURING AND ROADSTER FORMS

TWO BODY STYLES MOUNTED ON CHALMERS "36" CHASSIS—TOURING AND TORPEDO

Digitized by Google

ment which has been made and which scarcely can be listed as a change in construction, is to be found in the electric lighting system, which is of Gray & Davis manufacture. The dynamo is mounted on a bracket at the forward end of the engine and is driven by means of a V-belt, which serves also to drive the fan. The remainder of the system embraces the usual automatic cut-out for disconnecting the battery from the dynamo when the engine is idle, a storage battery of liberal capacity, and a complete complement of electric side, head, tail and dash lamps.

In the essential elements of the cars—namely, the motors, the clutches, the change gear mechanism and the running gears in general—no room for improvement has been found, and these parts are continued along the well tried out lines that were established when the cars first were placed on the market. The distinctive valve arrangement with the intake valves overhead operated by rocker arms and the exhaust valves at the side, is retained in all the models, the cylinders in the case of the "fours" being cast in single blocks and in the "six" in sets of three. Similarly cylinder dimensions have not been changed and remain 4 x 4½ for the "30," and 4¼ x 5½ in both the "36" and the six-cylinder model, which rates at 54 horsepower.



Ignition in each case is effected by means of a dual system using a single set of spark plugs. The constant level splash lubrication system is used in all the engines, the crankcase compartments being maintained at the proper level by means of a gear pump and the operation of the system being rendered visible through a sight feed glass located on the dash. In the smaller four-cylinder model, the three-speed change gear mechanism which has been used from the first is retained, the two larger cars being equipped with four-speed gearsets and all of them being selectively operated by right-hand levers.

Clutches all are of the multiple disk variety and operate in oil baths. Another slight change which has been made concerns the steering gear, which is larger and is fully enclosed in order to protect the parts from dust and dirt. The same column now is used on all the models, this feature being possible by reason of its construction, which permits of its adjustment over wide limits to suit the various bodies on the three chassis.

On the smaller four-cylinder model and the "six" the wheelbase remains the same —115 and 130 inches, respectively—though in the "36" it has been increased from 115 to 118 inches. Springs in each case are semi-elliptic in front and three-quarter elliptic in the rear. On the three chassis which go to make up the line no less than 14 types of body are supplied, the list including four-, five- and seven-passenger touring cars, roadster, inside driven coupe and limousine, prices in each case including as complete equipment as is necessary to suit the duty for which the car is intended. Demountable rims, top with dust cover, windshield, and electric lights are included in the equipment, which in the case of the "36" and the "six" also embraces the air engine starter.

Evolves Worm-Drive for Speedometers.

It may sound rather paradoxical, but nevertheless it is true that not a few speedometer troubles originate elsewhere than in the speedometer, and that while the instrument may be capable of performing its functions satisfactorily, it does not always do so. To be more explicit, irregularity of operation, unsteadiness of the indicating needle and even partial or total interruption of the function of indicating speed not infrequently are caused by imperfections in the mechanism through

RELIANCE SPIRAL DRIVE

which motion is transmitted from one of the road wheels to the speedometer, with the result that a speedometer that in itself is accurate and reliable may be regarded with suspicion, if not entirely discredited. A realization of this state of affairs has led the Reliance Speedometer Co., of 134 Eliot street, Boston, Mass., to develop the driving system shown in the accompanying illustration; so far as known it is the first spiral or worm transmission of the sort that has been evolved.

The most notable feature of the drive is the employment of spiral gears for transmitting motion from the short shaft carrying the driving pinion meshing with the gear on the road wheel to the flexible shaft which drives the instrument itself, and the elimination of friction and excessive wear by the use of ball bearings. The spiral gears and ball bearings, of course, are enclosed in a dust-proof casing, and lubrication is supplied by means of a grease cup of liberal size; there is a swivel joint which makes it possible to set the driving and driven shafts at any desired relative angle when installing the instrument. A feature that has obvious practical advantages is the ease with which the driving pinion can be removed and replaced with a new one. This pinion works under the most trying conditions, exposed to grit and mud, to say nothing of accidental damage from flying stones and the like, and quite naturally it is subjected to considerable wear. In the case of the Reliance mechanism, this pinion can be removed by withdrawing an ordinary split-pin and a new pinion attached by the reversal of this proceeding.

Throttle Opening that Prevents Choking.

As a "stunt" and for the purpose of testing carburetter adjustment, the sudden wide opening of the throttle is all well and good, and if the motor responds instantly without coughing or choking it speaks well for the operation and adjustment of the carburetter. But in actual road work it will be found that in nearly all cases the motor will pick up more rapidly and with better power if the throttle is opened gradually — not necessarily very slowly, but steadily and evenly. A little experimenting will indicate just how rapidly the valve can be opened, and this knowledge may be of the greatest value should the driver find himself in a position where the car must be accelerated with maximum rapidity. In such a case the impulse to throw the throttle lever to the end of its travel is strong, but it should be tempered with judgment and the carburetter given a chance to do its work properly.

Prisoner Devises a "Crook Catcher."

The old adage about setting a thief to catch a thief may not apply in all cases, but Lawrence T. Romer, an automobile mechanician who is serving a term in the Denver (Col.) county jail, unknowingly, perhaps, has lent color to the proverb by devising a scheme whereby the thieving "joy rider" may be thwarted before he even gets started on his trip. Romer proposes to attach his device, which may be set when the car is stopped and which will emit siren-like calls for help as soon as the would-be thief attempts to crank the car, the sound coming from an adaptation of a siren whistle located beneath the hood. The racket is calculated to be sufficient not only to cause terror to the thief but to attract attention to his contemplated deed. The arrangement will work as well in a garage at night as on the street.

Concerning Adjustability of Bearings.

Ball bearings and roller bearings in which no adjustment for wear is possible are so commonly used in motor car work that sometimes the fact is lost sight of that there are adjustable bearings of both classes. Adjustable roller bearings have tapered races and correspondingly tapered rollers, so that by moving the inner race ring further into the outer ring the surfaces upon which the rollers run are brought closer together, and so wear is taken up. The principle upon which ball bearings are adjusted is the same, and is exemplified by the old familiar bicycle bearings.

FARM TRACTORS SUBJECTED TO PRACTICAL TESTS

Annual Trials at Winnipeg Indicate the Decline of Steam and Ascendency of Gas Machines—Also Prove Tractor Design Almost Uninfluenced by Past Experience of Motor Car Engineers—How the Tests Were Conducted and the Many Awards That Were Made.

Prize winners were the rule instead of the exception at the Agricultural Motor Competition held in connection with the Canadian Industrial Exhibition at Winnipeg during the two weeks ending July 20th. Three prizes, consisting of gold, silver and bronze medals appropriately engraved, were offered in each one of the seven classes, and there were so many classes and so few entries in each class that those engines which came away without any of the jingling ornaments for souvenirs must have felt lonesome indeed.

The competition, of which the one just concluded is the fifth, is held annually under the auspices of the Exhibition Association during the Winnipeg Fair, and though ostensibly started to furnish the big wheat farmers of Western Canada with a basis on which to compare the performance of different makes and types of tractors. it has degenerated of late years into more or less of an advertising stunt for the tractor manufacturers. Hence the greater number of prizes and prize winners.

One thing the contest has shown, however, and that is the ever increasing superiority and popularity of the internal combustion engine as a source of farm power. In the first two contests the steam engines were in the majority and made by far the best showing in regard to fuel consumption and steady running. In 1910 the number of gasolene engines had exceeded the number of steam engines entered, and also succeeded in coming away with the most coveted prizes. In the last two years there has been another change, for both last year and this year the premier honors have gone to the engines using kerosene for fuel, and it looks as though they are now so far ahead in the matter of efficiency that there is no hope of the other types ever catching up again. As a matter of fact, one of the chief features of the 1912 contest was the number of internal combustion engines entered in both gasolene and kerosene classes, the same machine, in many cases, being adjusted to handle both kinds of fuel.

The official results of the tests, which have just been made public, though the contest has been concluded for over a week, show that the kerosene engines have come to the front again in this year's contest, with the gasolene motors showing the second best performance and the big steamers away at the foot of the class. According to the official data sheet, the Rumely "Oil Pull" kerosene tractor made the best showing in the various tests and lead the field with a score of 449.75 points out of a possible 500. An Aultman-Taylor gasolene engine was next, with a score of 447.7, and the best mark for a steam driven tractor was that made by the J. I. Case entry No. 27, which scored 442.85 points. These figures, of course, are entirely irrespective of classification, according to horsepower.

The complete tests of the competing engines were made in four separate divisions, designated as Economy Brake Test, Maximum Brake Test, Plowing Test, and Design and Construction.

AULTMAN-TAYLOR, A PRIZE WINNER

The economy brake test consisted in running the engines belted up to a Prony brake dynamometer for a period of two hours at their normal loads, while careful measurements were taken of the power output, fuel, oil and water consumption, steadiness of running, etc. For this test a total award of 190 points was possible, divided as follows:

	Internal Combustion.	Steam.
H. P. hours per unit of fuel.....	145	140
H. P. hours per unit of water.....	15	35
Steadiness, vibration and condition.	30	15
Total	190	190

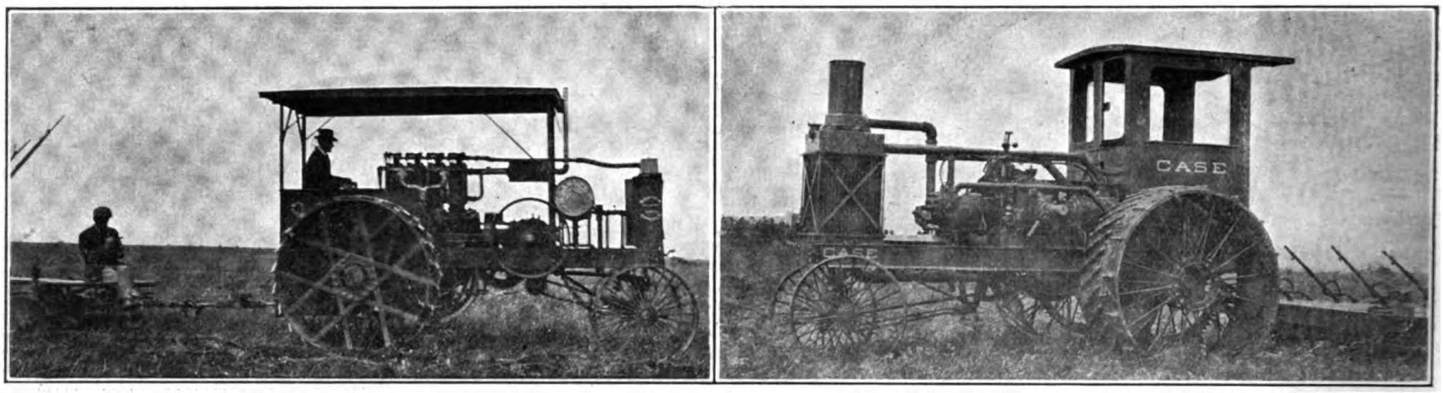
Maximum brake test figures were secured by operating the engines, belted to the brakes, at their maximum output for a period of thirty minutes while another set of observations was taken. This time the total possible award was 65 points, divided as follows:

Maximum load divided by economy load.....	35
Evenness of load.....	20
Condition of engine.....	10
Total	65

the figures being the same for both the steam and internal combustion engines.

Figures for the plowing test were obtained by sending the engines out in the country, where each was required to make four rounds of a three-quarter mile field of virgin Manitoba prairie sod, pulling an engine gang plow with the number of bottoms in proportion to the brake test load. Traction dynamometers were inserted between the engines and the plows and careful observations again taken as to the fuel, oil and water consumption. A total score of 215 points was possible in this test, divided as follows:

	Internal Combustion.	Steam
Drawbar H. P. hours per unit of fuel	140	120
Drawbar H. P. hours per unit of water	15	35
Acres plowed per hour per economy B. H. P.....	25	25
Quality of plowing.....	15	15
Distance traveled without replenishing fuel	10	5
Distance traveled without replenishing water	0	5
Condition of engine.....	10	10
Total	215	215



Points for design and construction were determined by the judges, who inspected each engine personally and made up the score, a total of 30 points being awarded as follows:

Accessibility	15
Protection of working parts.....	10
Ease of manipulation.....	5
Total	30

The figures in this case were also the same for steam and internal combustion motors.

For the contest this year the entries were divided into seven classes, two of which were for gasolene, two for kerosene, and three for steam tractors. There was to have been a third class, for gasolene engines under 15 horsepower, but as there were no entries this class was scratched. Class B was for gasolene tractors from 15 to 30 horsepower; Class C, gasolene over 30 horsepower; Class D, kerosene under 30 horsepower; Class E, kerosene over 30 horsepower, and Classes F, G and H were for steam engines. Four of the engines entered in the gasolene classes did double duty, as mentioned before, and went through the tests a second time burning kerosene. These were the Heer, entered as Nos. 1 and 2; the Avery, entered as Nos. 3 and 19; the I. H. C., entered as Nos. 9 and 21, and the Case, entered as Nos. 13 and 24.

SAWYER-MASSEY GASOLENE TRACTOR AND THE CASE GASOLENE, A FIRST PRIZE WINNER

Many of the best known and largest manufacturers of tractors in the United States and Canada were represented with one or more entries, though it was notable that neither the Gas Traction Co. of Minneapolis nor the Kinnard-Haines Co., of the same city, both winners of former contests, were present. The entrants and their classification is given in the score sheet appended, and a list of the winners in the respective classes appears at the beginning of this article.

The judges of this contest were Prof. L. W. Chase of the Nebraska Agricultural College, Prof. M. L. King of the Iowa State College, and Prof. A. R. Greig of the Saskatchewan University. Arthur C. Frith, a consulting engineer of Winnipeg, acted as engineer in charge, and the officials were assisted in their work by a number of observers appointed by the different concerns taking part in the contest. Their awards were as follows:

Class B.—Gasolene Tractors—1st, J. I. Case T. M. Co. No. 4; 2nd, Goold, Shapley & Muir No. 5; 3rd, Avery Co. No. 3.

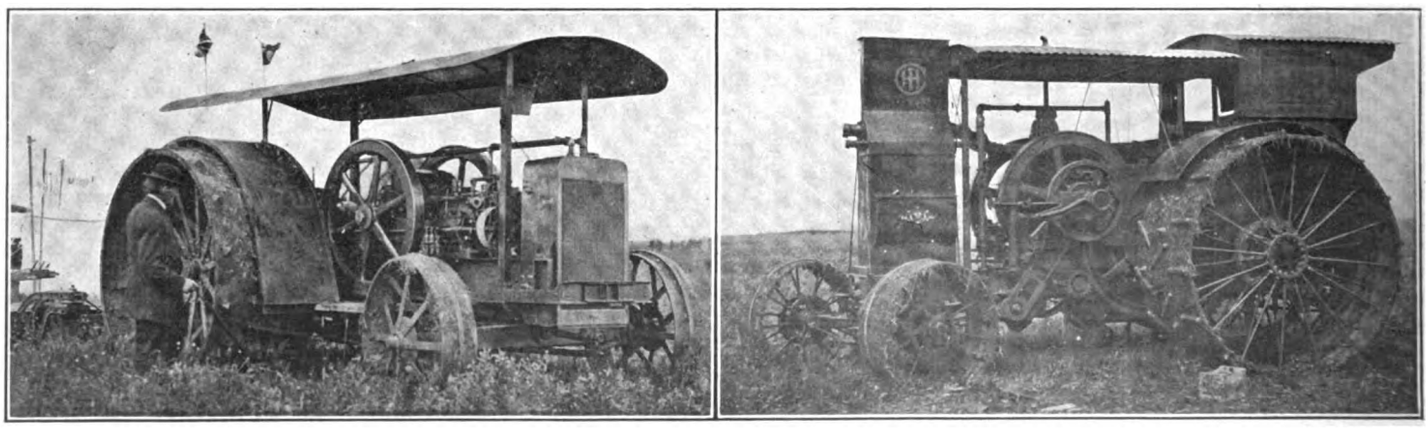
Class C.—Gasolene Tractors—1st, Aultman-Taylor Co. No. 12; 2nd, I. H. C. No. 8; 3rd, Holt Caterpillar No. 11.

Class D.—Kerosene Tractors—1st, I. H. C. No. 18; 2nd, Rumely Products Co. No. 16; 3rd, Avery Co. No. 19.

Class E.—Kerosene Tractors—1st, Rumely Products Co. No. 23; 2nd, Aultman-Taylor Co. No. 22; 3rd, I. H. C. No. 21.

Class F.—Steam Tractors—1st, J. I. Case T. M. Co. No. 25. No competition in this class.

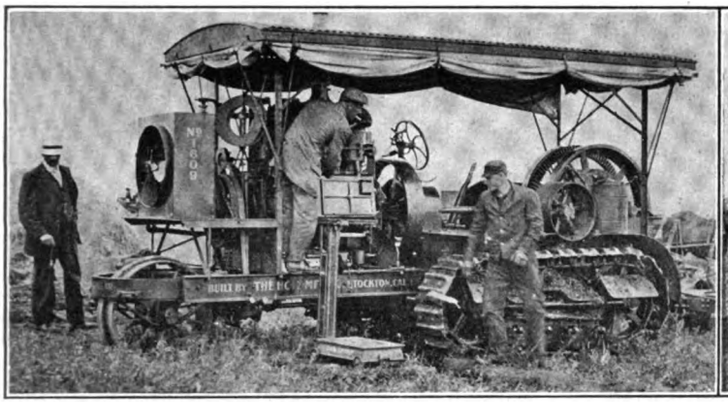
Class G.—Steam Tractors—1st, J. I. Case T. M. Co. No. 26. No competition.



Class H.—Steam Tractors—1st, J. I. Case T. M. Co. No. 27; 2nd, Sawyer-Massey Co. No. 29. Only two entered.

Official entry blanks sent out before the contest announced that the tests would start on July 3rd, but in reality nothing was attempted until the next day, when one lone engine was introduced to the brake and its tests run off. The real start was made on July 5th, when two brakes were put into operation in the shed built for that purpose on the fair grounds, and four engines were put through their initial trials, the judges and officials working from 7 A. M. to 10 P. M. or later without even a stop for lunch. This performance was repeated every day for the next five days, no tests being run on Sunday. It was July 11th before all the engines had completed the brake tests, and plowing was not begun until July 16th, owing to rain and a delay caused by the Exhibition management, who had advertised that the plowing tests would be in full swing during the second week of the fair.

From the standpoint of the automobile engineer, the contest was almost featureless, especially as regards anything new being brought out in the design or construction of the competing engines. The steam engines were all of the same type, a type which has become pretty well standardized through many years of use—that is, with single, double-acting cylinder mounted on brackets attached directly to the horizontal fire-tube boilers carrying from 100 to 150 pounds steam pressure and using soft coal for fuel. The test was hardly representative in this case, because as used in the field a majority of the engines are fired with wheat straw or flax straw, especially during threshing operations, and it can hardly be assumed that the performance on the various fuels will be comparable.



This year there was a notable absence from the contest of gasolene or kerosene tractors equipped with four-cylinder power plants of the automobile type, though motors of this type had been successful in winning the chief prizes both in 1910 and 1911. On the other hand the big, horizontal single-cylinder stationary type engines which were so prominent a year or two ago have almost disappeared. The standard type now in use seems to be the two-cylinder opposed engine, a design which was long ago abandoned by automobile engineers in favor of the vertical motor.

One of the most interesting machines, from a mechanical standpoint, was the entry of the Canadian Holt Co., a subsidiary of the Holt Caterpillar Co., of Peoria, Ill. This tractor was of the "caterpillar" type, using an endless chain-belt running over sprockets instead of the conventional driving wheels. It was equipped with a large four-cylinder Buick type motor with

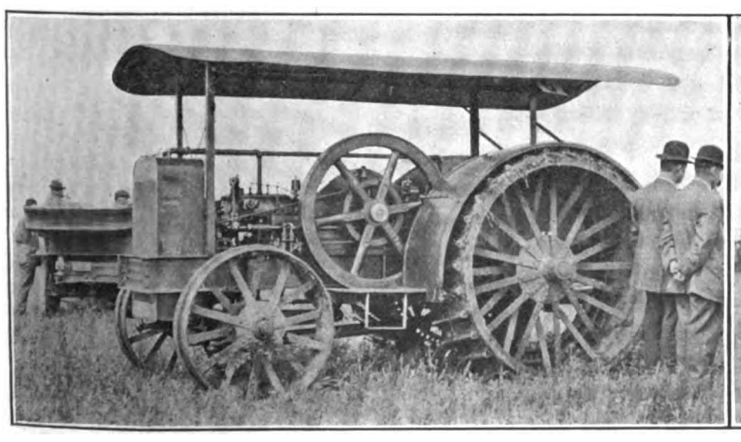
HOLT GASOLENE "CATERPILLAR" IN CLASS C

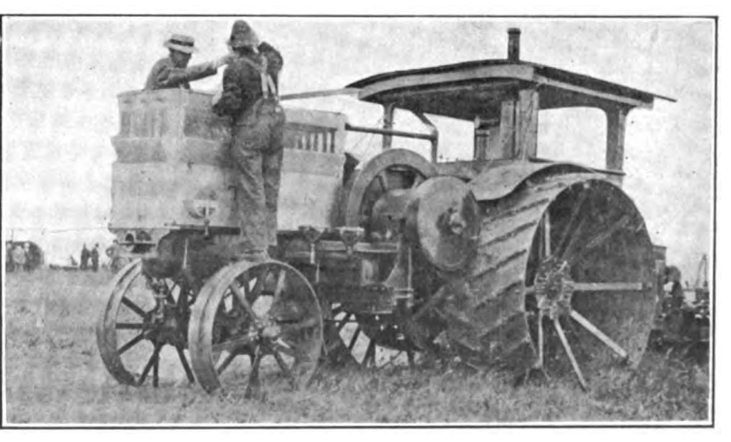
AVERY GASOLENE TRACTOR IN CLASS B

caged valves in the head, and power was transmitted from the engine through a two-speed gearset to a jack-shaft geared to the driving sprockets. There was no differential, but individual friction clutches provided for driving by one "caterpillar" at a time when turning corners. This machine secured the third place in Class C.

Another peculiar machine was the tractor entered by the Canadian Heer Engine Co., and manufactured by the Heer Engine Co., of Portsmouth, Ohio. It has a two-cylinder opposed engine mounted under a long hood in front, with a radiator forward, a la automobile, but its peculiarity lay in the chain drive. The driving chains are ordinary link log-chains transmitting power from the countershaft to sprockets on both axles. Both axles are live and both are driven and steered. The sprockets are connected to the live axles by universal joints which allow the axles to turn through a small arc without disturbing the alignment of the driving sprockets. This machine was entered in Class B and Class D, burning gasolene in the one and kerosene in the other, but failed to secure official recognition in either class.



The six engines entered by the International Harvester Co., of Chicago, were all of their standard types which have been on the market for some time and are too well known to need much description. Three of them were of the twin cylinder, counterbalanced type, one was a single cylinder machine, one a twin vertical, and the other a double opposed. Any of them are fitted to handle either gasolene or kerosene by a simple change of the mixing valve. One of the engines in the kerosene class was later withdrawn on account of unsatisfactory adjustments made apparent during the brake test. They secured first place in Class D, a second in Class C, and a third in Class E.



The Rumely Products Co., of La Porte, Ind., had entered three engines of the "Oil Pull" type in the kerosene divisions, two of them differing only in the construction of the cylinder heads, while the third was of a smaller size. Of the two tractors entered in the 30-60 horsepower kerosene class, the judges ruled one out on the ground that the difference between the T-head and L-head cylinders was not sufficient to overcome the ruling against any maker entering two machines of the same type. All of the "Oil Pulls" are of either the twin-cylinder or single-cylinder type, with heavily counterbalanced crank-shafts and fitted with the Secor carburetter, which uses kerosene in conjunction with water injection. It is claimed that the small quantity of water injected with each charge of kerosene keeps down the initial temperature of the explosion, raises the final temperature of the expanding gases and prevents the formation of carbon deposits from the low grade fuel.

In former years the Avery Co., of Peoria, Ill., has been represented in the contests by a light tractor of the motor truck type, fitted with a small four-cylinder vertical engine under the bonnet and special lugged driving wheels to give it traction in the soft ground. This year the little machine was absent, however, and the Avery Co. had but one tractor, which did duty in both the kerosene and gasolene classes, winning a third prize in each. It consisted essentially of a double-opposed motor mounted on a heavy frame and geared through the counter shaft and differential to big driving wheels at the rear.

The Aultman-Taylor Co., of Mansfield, Ohio, was present with two tractors of the twin-cylinder type, one of which competed in the gasolene division and the other in the kerosene class. The one in Class C took first place and the one in Class E took second, which was a very good showing considering that only the two were entered.

The J. I. Case Threshing Machine Co., of Racine, Wis., was represented by two internal combustion and three steam engines. Each of the steamers took first prize in its class, there being no competition in two of the classes. Of the internal combustion engines, one was a two-cylinder opposed using gasolene and the other a twin, burning kerosene. The gasolene engine took first prize in Class B, but the kerosene tractor failed to score, though it also did double duty and used both fuels.

TWO SECOND PRIZE GASOLENE-PROPELLED WINNERS—GOOLD, SHAPLEY & MUIR AND I. H. C.

Digitized by Google

The entry of the Diamond Iron Works of Minneapolis was one of the few tractors having automobile type power plants, and it failed to score in the heavy gasolene class in which it was entered.

Goold, Shapley & Muir of Brantford, Ont., was one of the two Canadian firms represented at the trials, and they had entered two tractors of the double opposed type—one a 22 horsepower machine in Class B and the other, which was rated at 45 horsepower, in Class C. The Class C entry was later withdrawn for some unknown reason. The smaller engine, however, completed its tests, taking second prize for its performance in Class B.

The only other Canadian manufacturer represented was the Sawyer-Massey Co. of Hamilton, Ont., who entered one gasolene and one steam tractor. The steam tractor took second to a Case machine, the only other entry in Class G, and the gasolene machine failed to score in Class C, where it

AMERICAN GAS TRACTOR

was entered. It was another of the few four-cylinder machines, but its engine was set transversely on the frame amidships.

Besides the engines in the contest, there were several non-competitors demonstrating near the plowing grounds, among which may be mentioned the "Pioneer 30," manufactured by the Pioneer Tractor Co., of Stillwater, Minn., and the Hackney Auto Plow, made by a St. Paul concern. The "Pioneer" resembled a big automobile of the enclosed type more than anything else, with its automobile radiator and long sloping hood concealing a four-cylinder vertical motor. An enclosed driver's cab at the rear made the illusion complete. The Hackney plow most nearly approaches present-day automobile construction. It has the plows fastened directly on the main frame between the front and rear wheels and directly under the four-cylinder motor. It had only one driving wheel behind and two steering wheels in front.

As to the general points of design in which the tractors compare with current automobile practice, there are practically none outside of the few unimportant features already noted. Several of the machines at Winnipeg displayed tubular radiators for cooling water, but these were very large and quite crude. Many of the engines were equipped with square or round tanks with a few tubes through the center into which the exhaust gases were passed to induce a draft, in lieu of a fan. Carburetters, as the word is generally known in the automobile business, were nowhere in evidence except on the few automobile type motors in use, most of the engines using specially designed mixing or

HACKNEY AUTO PLOW

vaporizing valves, some of which were arranged to use water in conjunction with kerosene. Transmissions were also rather crude affairs, most of them being simple reverse gears, but in one or two cases two forward speeds were provided. Most of the large tractors are designed to travel at speeds of from 1.5 to 2.5 miles per hour when plowing. One manufacturer exhibited a gang-plow in which the bottoms were so attached to an axle driven by the land wheels that the movement of a lever auto-

PIONEER "30"—A NON-CONTESTANT

matically raised the whole twelve or fourteen in succession, thus leaving the furrow even at the end.

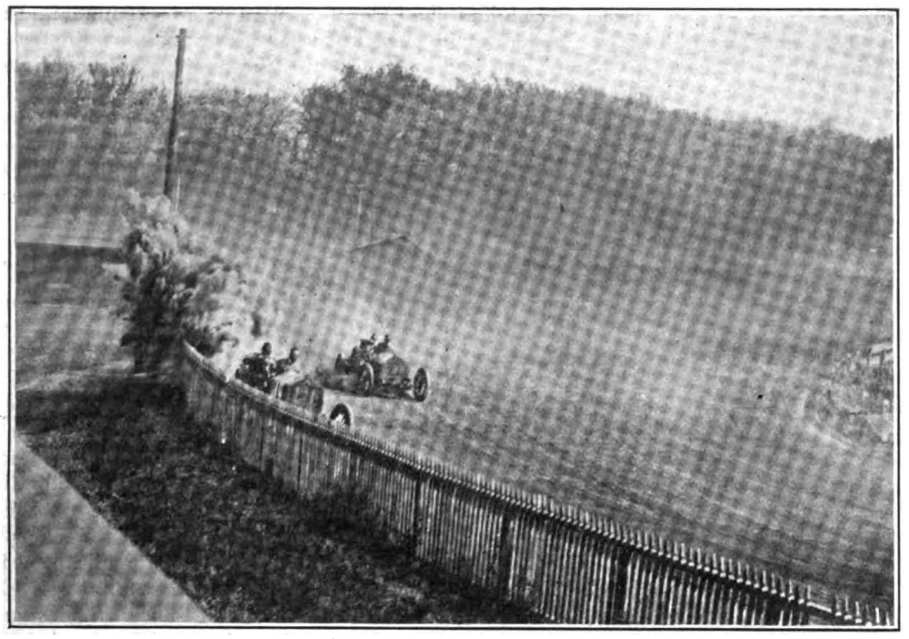
It was a notable fact that, while in former contests the hit-and-miss type of governor has been prominent, especially on the twin-cylinder machines, it has now been largely succeeded by the throttling type, which gives much steadier running, especially on the brake. Driving wheels are all of very large diameter, some of them being six or eight feet high, and spur gear transmission is the general rule. Very few of the machines were mounted on springs of any kind, though in one or two cases there had been an attempt to use very heavy spirals.

In steering gears, the old pivoted front axle, with chain and wheel control, seems to persist on most of the machines, but one or two of the newer ones exploited knuckle steering devices. An interesting development of this arrangement is to be seen in the various automatic steering gears which have made favorable headway during the past few years, and which consist generally of a small pilot wheel running ahead of the engine in the last furrow of the former round, and connected by link work to the front axle or steering gear. It was also remarkable how straight a furrow some of the more experienced operators were able to strike across the three-quarter mile field, despite their unwieldy mounts.

While the contest is supposed to be a part of the Winnipeg Industrial Exhibition and the brake tests are carried on within the fair grounds enclosure, it is doubtful

HEER FOUR-WHEEL DRIVE TRACTOR

if the plowing competition forms much of an attraction, on account of the extreme difficulty of getting to the grounds and back. This year the exhibition management provided a special train service on the Canadian Northern Railway to take the spectators out to the plowing field, which was a good 15 miles from the city. The train service was so very intermittent in character, however, that one never knew when a train would leave or how soon he could get back, and as there was nothing in the shape of food or drink to be obtained near the grounds, the ones who ventured out generally went hungry. The story is told of two of the judges who missed the last train and spent the night supperless, in a leaky tent, with a tank wagon and several barrels of oil for bedfellows, while a heavy rain absolutely precluded the possibility of getting an automobile or other vehicle to the scene.



This year there has been considerable talk among the manufacturers' representatives of changing the base of operations from Winnipeg to Peoria, Ill., where the directors of the National Implement and Vehicle Show are said to be anxious to have a competition of their own.

WHALEN ALMOST "WHOLE SHOW"

Captures Three Events at Wilkes-Barre Meet—All That He Left Are Shared by Three Others.

Neil Whalen, the National pilot, had things all his own way at Wilkes-Barre, Pa., Saturday last, July 27th, where E. A. Cusick offered an eight-sided program on the West Side Driving Park track. In three of the four competitive events in which he drove he led home all other contenders and also made the best time for a single mile, driving the National twice around the half-mile track in 1:15¼.

WHALEN HAS A CLOSE CALL IN THE 10- MILE EVENT

Two Class E events, both of which went for five miles, for cars with displacements under 451 and under 600 inches, respectively, Whalen completed in 7:08 and 7:05, respectively, while the ten-mile free-for-all he decided in 14:05⅘. In the five-mile free-for-all handicap, however, Whalen took only third place, first honors falling to the share of William Burke (E-M-F), who completed the distance in 7:04⅗. John DePalma (Mercer) took second position. William Williams, who guided the Buick entry in the Class E event for cars with displacements under 231 inches, made the best time for the three miles, covering the distance in 4:21½. A five-mile Class E event for cars with displacements under 301 inches was completed by Harvey Ringler (Mercer) in 7:09⅕. A single mile exhibition driven by John DePalma at the wheel of the Mercer in 1:23 marked the close of the meet.

Although considerable work in the way of "manicuring" the track had been performed so that a repetition of the events of the week before, when a race meet staged on the same track by E. A. Moross had to be curtailed because of the dust, would not be necessary, the applications of water, oil and $CaCO_3$ did not leave the track entirely free from the nuisance. When a car swung unduly wide, a great cloud was kicked up, but as the traveled portion of the course was relatively good, no accidents resulted. The summary:

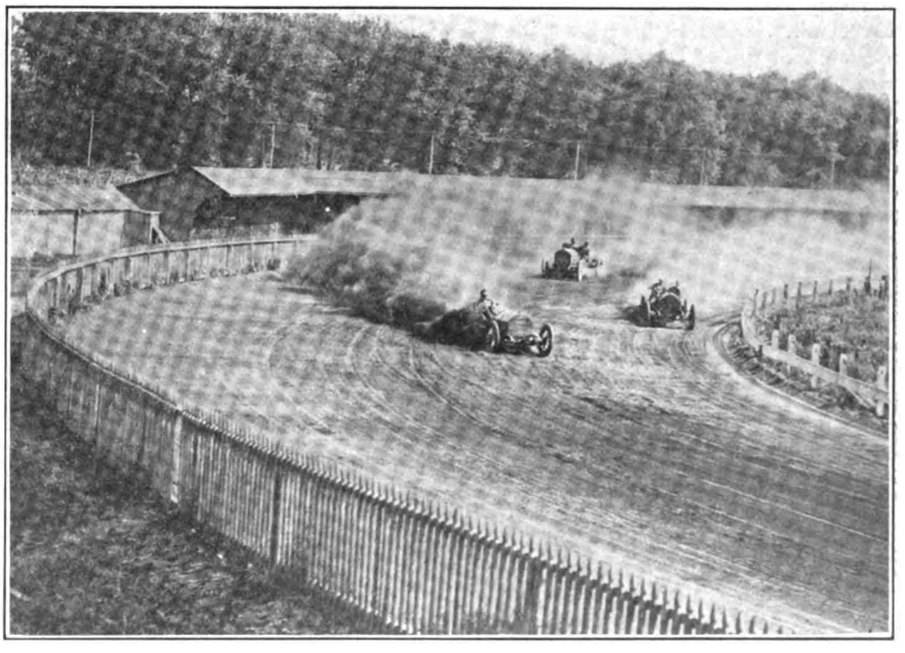
Three miles, Class E, for cars with displacements under 231 inches—Won by William Williams (Buick); second, William Burke (E-M-F); third, Fred Douglas (Ford). Time, 4:21½.

One mile, time trial—Neil Whalen (National). Time, 1:15¼.

Five miles, Class E, for cars with displacements under 301 inches—Won by Harvey Ringler (Mercer); second, John DePalma (Mercer). Time, 7:09⅕.

One mile, time trial—John DePalma (Mercer). Time, 1:23.

Five miles, Class E, for cars with displacements under 451 inches—Won by Neil Whalen (National); second, Harvey Ringler (Mercer); third, John DePalma (Mercer). Time, 7:08.



Five miles, Class E, for cars with displacements under 600 inches—Won by Neil Whalen (National); second, John DePalma (Mercer); third, William Freitag (Marmon). Time, 7:05.

Ten miles, free-for-all—Won by Neil Whalen (National); second, Harvey Ringler (Mercer); third, John DePalma (Mercer). Time, 14:05⅘.

Five miles, free-for-all, handicap — Won by William Burke (E-M-F); second, John DePalma (Mercer); third, Neil Whalen (National). Time, 7:04⅗.

Whalen and Williams Divide at Scranton.

Honors were pretty well divided between William Williams, who piloted a Buick car, and Neil Whalen, who was at the wheel of a National, at the race meet in Scranton, Pa., on Wednesday, July 24th, promoted by E. A. Cusick. Two events went to the Buick pilot, while Whalen took all save one of those that remained on the seven-event program. The odd trick went to John DePalma, who drove an exhibition mile in his Mercer in 1:20⅗. The summary:

JOHN DE PALMA (MERCER) LEADING IN THE FIVE-MILE RACE

Three miles, Class E, for cars with displacements of under 231 inches—Won by William Williams (Buick); second, Fred Douglas (Ford). Time, 4:32⅖.

One mile, time trial—Neil Whalen (National). Time, 1:20.

Five miles, Class E, for cars with dis-

Digitized by Google

placements of under 301 inches—Won by William Williams (Buick); second, Harvey Ringler (Mercer); third, John DePalma (Mercer). Time, 6:30.

One mile, time trial—John DePalma (Mercer). Time, 1:20⅗.

Three miles, Class E, for cars with displacements under 451 inches; first heat—Won by William Williams (Buick); second, Joe Foster (Marmon); third, E. F. Stein (Buick). Time, 4:02¼. Second heat—Won by Neil Whalen (National); second, John DePalma (Mercer). Final heat—Won by Neil Whalen (National); second, Joe Foster (Marmon). Time, 4:06.

One mile, time trials—William Williams (Buick). Time, 1:20⅗. William Freitag (Fiat). Time, 1:14. Fred Douglas (Ford). Time, 1:35.

Five miles, Class E, for cars with displacements of under 600 inches—Won by Neil Whalen (National); second, William Williams (Buick); third, John DePalma (Mercer). Time, 6:52.

Burman has a Big Day at Rochester.

Moross routine, with but one variation, was followed at the race meet run on the Critten Park track, Rochester, N. Y., on Saturday last, July 27th, under the auspices of E. A. Moross. The variation was caused by William Knipper, who drove a Benz car in the two-mile free-for-all handicap into first position, his time being 3:12⅖, The other four events which went to make up the program went to Burman. The summary:

Three miles, Class E, for cars with displacements of under 600 inches—Won by Burman (Cutting); second, Kyle (White); third, Sutton (Schacht). Time, 4:04.

Two miles, for the Remy Brassard and trophy; first heat—Won by Robert Burman (Benz); second, MacDonald (Benz); third, Hickman (Mercedes). Time, 2:35. Second heat—Stopped when Hickman (Mercedes) went through the fence. Third heat (one mile)—Won by Robert Burman (Benz); second, Hickman (Mercedes); third, Kyle (White). Time, 1:29.

One mile, time trial—Burman (Benz). Time, 1:08.

Three miles, Class E, for cars with displacements of under 600 inches—Won by Burman (Cutting); second, Kyle (White). Time, 4:09⅖.

Two miles, free-for-all, handicap—Won by William Knipper (Benz); second, Kyle (White); third, Sutton (Schacht). Time, 3:12⅖.

Police Chief Proposes Sealing Cut-outs.

Chief of Police Carter of Columbus, Ohio, is one deadly enemy of the muffler cut-out and is causing gratification in the hearts of others who fail to see any necessity for making an automobile "bark like a dog" by an ordinance which he proposes to have introduced in the city council requiring muffler cut-outs to be officially sealed and making it a misdemeanor to be found with such a seal broken. The proposed seals would be little lead arrangements and would be put on for 50 cents by an official sealer. Should a seal be broken while in the country the car may proceed into the city, but at once must be "re-sealed." The measure would cover motorcycles as well.

Waddington, he Saddles his Motor Car.

If photographs do not lie, Bob Waddington is something of a wonder. Waddington is a ranchman, likewise a cowboy, who claims Cisco, Tex., as his home. He is an up-to-date chap, as his possesison of a Cole car, which he has driven for 28,000 miles, serves to indicate. Of course, mere possession of a motor car is not wonderful, but, if you will believe it, Waddington has transferred a saddle from the back of a broncho to the bonnet of his automobile, and they do say that the way he can rope

WADDINGTON BEFORE THE CAMERA

a steer while seated astride a hot engine is a sight to behold. The accompanying photograph shows the saddle so positioned, but when he faced the camera Robert deemed it wise, or at any rate picturesque, to "stand on his feet" when he let loose the lariat; but it is safe to say that he does not rope many steers when standing in that position while bounding over the bounding prairies of Texas. When Robert first placed the saddle on the Cole bonnet, it is stated that his friends laughed.

Elephant Yarn of Elephantine Proportions.

Every story which emanates from the jungle of a distant country generally is tinged with a bit of suspicion as to authenticity, and when an English newspaper prints the tale of how an elephant was captured on the Island of Sumatra by a native of Switzerland and was then given an automobile ride to the place of his captivity, every man must be his own judge of the reliability of the source of information. "The elephant, which was well roped," says the report, was driven to the nearest path in the forest, and with great difficulty the motor car arrived at the spot, a kind of platform replacing the body. The elephant was induced to mount the platform and was strongly secured to it. The trip to Siantar started, but difficulties at once arose, because the elephant, whose trunk was free, used it to examine in turn the chauffeur, the seats in front, the machinery, and finally the guiding wheel, his last maneuver nearly upsetting the car, which was brought to a stop, as the journey was becoming dangerous. The elephant's trunk was then strapped to his body and the car arrived at Siantar without further incident."

Disbrow's Clean-up at Michigan Meet.

Louis Disbrow, who at various times during the day piloted a Simplex, a Case and the rebuilt racing machine "Jay-Eye-See," practically swept the boards clean at the race meet which was run on the Comstock Park track, Grand Rapids, Mich., Saturday, July 27th, and which was fathered by the Grand Rapids Automobile Club. He accounted for all save one of the seven events on the program; the exception, a three-mile free-for-all handicap, was won by Joe Nikrent (Case) in 3:49.10, with Disbrow in second place. The summary:

One mile, time trials—Louis Disbrow (Case), time, 1:30; William Endicott (Schacht), time, 59:75; Joe Nikrent (Case), time, 1:01.30; Louis Disbrow (Jay-Eye-See), time, 58:40; Louis Disbrow (Simplex), time, 54:55.

Five miles, for cars with displacements of 231-300 inches—Won by Louis Disbrow (Case); second, Wm. Endicott (Schacht); third, Joe Nikrent (Case). Time, 6:05.70.

Ten miles, time trial—Louis Disbrow (Simplex). Time, 9:08.5.

Four miles, Australian pursuit—Won by Disbrow (Simplex). Time, 3:59.10.

One mile, time trial—Louis Disbrow (Jay-Eye-See). Time, 57:95.

Three miles, free-for-all, handicap—Won by Joe Nikrent (Case); second, Louis Disbrow (Case); third, William Endicott (Schacht). Time, 3:49.10.

One mile, time trial—Louis Disbrow (Simplex). Time, 53:60.

Jersey's Tags to be Maroon and White.

Fancy colors of the college variety and combination are to be abandoned in New Jersey in the enameling of the state automobile license tags because, as State motor vehicle commissioner Job H. Lippincott says, he has used up all the combinations extant with the exception of scarlet and black, and the commissioner doubts the advisability of using these colors because of the likelihood that the numerals would not be very easily distinguishable. He has, after deliberation, selected white and maroon as the scheme for the 1913 tags, the field to be white and figures maroon.

FIFTEEN TIE FOR TEXAS TROPHY

And As a Result, Lottery Decides Award in Farmers' and Ranchers' Tour—Others Receive Real Money.

Neither the limestone roads of Texas, which are very prolific with regard to fine dust and small, sharp stones, nor the speed ordinances in force in the towns passed en route, could have kept even the most conservative contenders in the Farm and Ranch tour, which started from Dallas on the morning of Monday, July 22nd, for a six-day run, from reaching the half-way point, San Antonio, two days ahead of schedule, had it not been for the fact that the pacemaker was a "strong-arm" man. His athletic propensities, however, were not at all times equal to the task of curbing the desire for speed of the most ambitious of the ranchmen, so that on the afternoon of the first day it was necessary for him to chase one of the contenders who had slipped past him at Hillsboro, the noon control, for five miles and inform him that he was participating in a tour, not a road race. Waco, the night control, slightly over 100 miles from the starting point, was reached hours before schedule time, but without mishap or penalty to any of the contenders.

The tour, which was the first of its kind and wholly devoid of trade influence, embraced a course some 650 miles in extent leading to San Antonio by way of Waco and Austin. The return, however, was made by way of Taylor and Mexia. The tour was conducted under Grade IV rules, by which contestants are penalized only for being late at controls and for work done on the motor while on the road.

The second day's run practically was a repetition of the first leg, the 132 miles to Austin being covered in good season without mishap or penalty. Wednesday evening saw the contenders in San Antonio, 82½ miles from Austin. The going had not been so smooth on the third day of the journey, but despite the fact but three of the 27 contenders failed to finish with clean slates.

Thursday evening saw the tourists in Taylor after an uneventful 100-mile run from San Antonio, the route having led them through San Marcos and Austin. On Friday, July 26th, the longest and hardest day's run—145 miles, from Taylor to Mexia—was covered, but not without mishap. Most of the penalties which were attached to the 12 contenders who failed to finish with clean score boards, were earned on this leg of the journey. Several, however, who had covered the five-days' route without mishap tripped up on the last 100 miles of the tour, from Mexia to Dallas.

In all, 15 of the contenders finished with clean scores, so that the disposition of the silver trophy offered by Col. F. P. Holland to the contender who made the best showing, had to be determined by drawing lots. W. H. Camp, of San Gabriel, who had piloted a Reo car, drew the prize. The other 14 contenders who had had a claim on the trophy before the lots were drawn, were not totally unrewarded, however, for the $900 in gold which was to have gone as 5, 3 and 1 to the contenders with the three best scores, was divided among them, each man receiving $64.27.

The 15 who drew for the trophy were: W. R. Bishop, Franklin; J. M. Howe, E-M-F; W. R. Mickle, Chalmers; J. R. Pennington, Buick; R. B. Dunn, Mitchell; B. W. Bean, Studebaker; D. W. Rutherford, Maxwell; O. L. Sims, Overland; J. Mantel, Hudson; H. V. Hendrick, Buick; S. J. Hall, Hupmobile, W. H. Camp, Reo; W. R. Newton, Ford; R. G. Roach, Ford; L. B. Blair, Maxwell.

Banquet Tops off Four States Tour.

Thursday evening, July 25th, witnessed 80 weary, sunburned but optimistic tourists, erstwhile participators in the annual Four States Tour of the Indiana Automobile Dealers' Association, gathered around the festive board at the German House, Indianapolis, partaking of a "dutch" supper and making merry generally. It was in the nature of a finishing touch to the two-weeks "boosting Indiana" expedition. During the course of the evening the heartfelt thanks of each and every member of the party were tendered to the officials of the tour, D. S. Menasco, J. M. Ward and W. D. Edenburn, to whom the success of the tour was attributed. At the conclusion of the speech-making, which was not continued sufficiently long to become wearisome, and during which it was disclosed that between 70 and 80 cars had been disposed of by the various agents during the tour, besides which many good "leads" were obtained, together with considerable advertising of the "worth-while" variety, the tourists were entertained by a vaudeville performance.

Token that Relieves Roadside Distress.

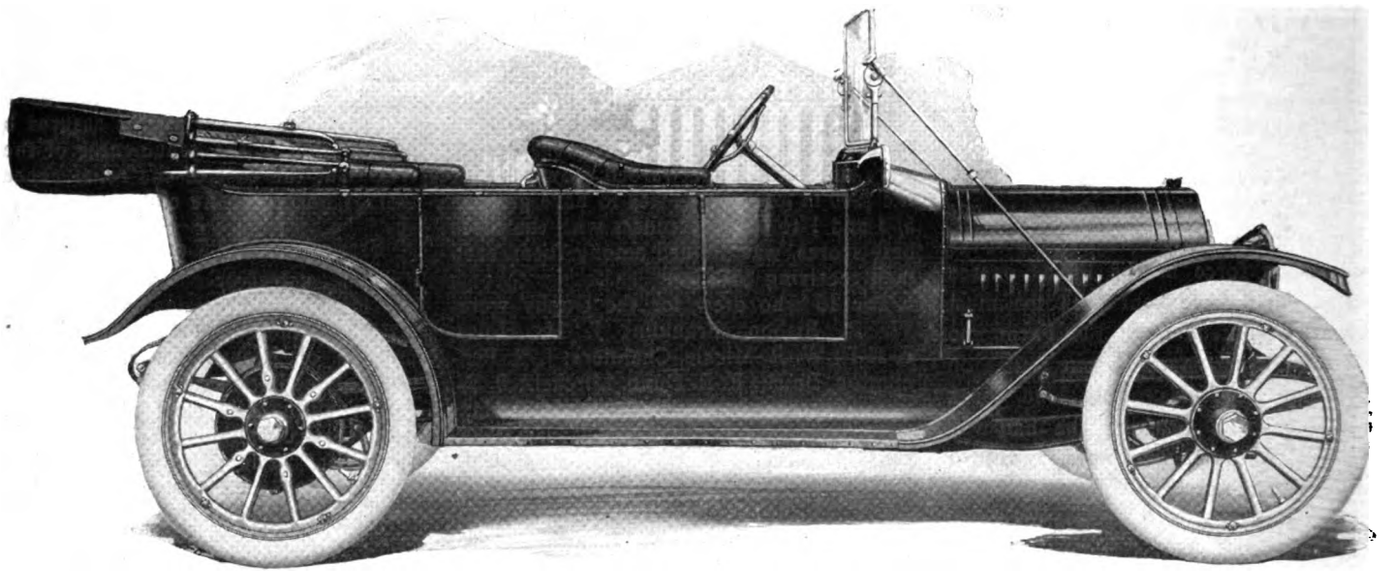
Marking either a delicate tribute to the dependability of the automobile, or philanthropy that is out of the ordinary, the General Committee of the Royal Automobile Club of Great Britain has developed a scheme which should result to the material advantage of members and associate members who are periodically followed by a "jinx," even if it does deplete the club's treasury. The scheme, briefly, is to provide members and associates with a token the exhibition of which in the case of trouble will ensure quick relief from any of the numerous R. A. C. repair stations that dot the country. The modus operandi provides that in case of breakdowns the token must be sent by the most convenient messenger to the nearest repair station, when a repair car equipped to tow the disabled car to the shop or to convey the passengers a reasonable distance to their homes or headquarters or to a railroad station will be dispatched at once to the scene of the trouble. Not only will the token secure the immediate attention of the R. A. C. repair station, which will be assured by its presentation of the genuineness of the distress, but the cost of the relief expedition will be borne by the club.

France Forms "Le Club des Cent."

Taking a leaf out of an American book, the idea having originated with the formation of the 50,000-mile Maxwell club, a number of French enthusiasts who are residents of Paris and environs have formed a new automobile club which has as its somewhat unenlightening title "Le Club des Cent." The designation implies that the maximum membership is limited to 100. Eligibility requires that each prospective member shall have covered in an automobile 40,000 kilometers, which is equal to 24,854 miles and is, approximately, the circumference of the earth. In addition to this qualification, it is said that the club will be very exclusive and will be recruited "from the elect of the worlds of politics, art and commerce."

Imprisoned for Murder, Acts as Chauffeur.

Many instances are cited of ex-convicts being the operators of taxicabs, but that a bona fide penitentiary prisoner, and one serving time for murder at that, should be a chauffeur is the story which finds origin in the penitentiary at Columbus, O. The prisoner is Bushrod Kelch, who was sentenced to 20 years from Cleveland, and, being a "trusty," he is employed to drive the institution's motor truck, which was delivered last Saturday, July 27, between the "pen" and the prison farm at Orient, some distance away, thus placing himself in a different class than those "trusties" who are compelled to be content as drivers of horses.



To Attach Taxicab Bandit's Car.

Geno Montani, the taxicab operator whose car was used several months ago in a sensational robbery of a bank messenger in New York City, may lose his car through the transaction. A sheriff's jury on Monday awarded a writ of execution in favor of the East River National Bank, the loser of the funds, and besides being directed against the robbers and jewelry they are said to possess, the paper may be the means of taking the taxicab as well. The amount stolen was $25,000, $3,965 of which has been recovered.

Minneapolis Tour Postponed Two Weeks.

Because of the tardiness in receiving the sanction for the event from the contest board of the A. A. A., the annual reliability tour of the Minnesota State Automobile Association, which was to have left St. Paul on the morning of July 25th, the start was postponed until Thursday, 8th inst. The route will lead to Winnipeg and return and will be covered in seven days.

We Believe This is the Best Car Ever Offered for $1800

We believe there is more actual car value—to the owner—more actual use and comfort to be had from the Dreadnought Moline M-40 than was ever before given at the price.

This is truly a wonderful car—Its nearest competitor at any price cannot show more added features of intrinsic merit in their latest models.

We will be believed because we have always built a good car—and because we have always made conservative statements.

The unapproached record of the Dreadnought Moline in Reliability and Economy Events makes this—our 10th—season with our splendid refinements and equipment more than ordinarily interesting.

Read of the 20 exceptional features of this handsome model M-40 of the famous Long Stroke Motor.

Dreadnought Moline

20 EXCEPTIONAL FEATURES OF THE M-40

10-inch more Wheel Base. (124")	Inside Control	Prest-O Self Starter
Electric Lights	Ten-Inch Upholstery	Large Wheels and Tires
5 more Horsepower. (Full 40)	Turkish Spring Cushions	Exceptionally Roomy Body
Improved Steering Gear	Flush Side Bodies	Demountable Rims (set of five)
Gasoline Tank Under Cowl	Nickel Trimmings	Dual Ignition System
Indicator and Filler on Dash	Long Stroke Motor—40-H.P.	Carburetor Dash Adjustment
Improved Springs	Enlarged Brakes	Rain Vision Windshield

These are simply features and refinements added to the famous Dreadnought Moline—the car with the three point suspension and the unit power plant, in which is housed the Dreadnought Moline Long Stroke Motor—40 H.P.—the first of its type built in America.

No car sold at this price has ever approached the Dreadnought Moline M-40 in the luxury and comfort of its appointments, the completeness of its equipment; in reserve power, the bull-dog tenacity of its long stroke motor on grades; its ease of control in crowded traffic; or its official record of victories in sanctioned Reliability and Economy Runs.

Many of the features here named you will find only on the highest priced cars. We want you to know how much these features mean to you whether you are a prospective owner or dealer.

We have printed a catalog that is interesting—that will not bore you—that tells the things you want to know about the car you will some day buy.

Don't wait for further announcements. Write today for the most interesting catalog ever written—about the most interesting car that was ever built.

DEALERS: Write for our "square deal" proposition and open territory. We can interest you.

MOLINE AUTOMOBILE COMPANY, 61 Keokuk St., EAST MOLINE, ILL.

1,012,879. Gripping Device for Securing Auxiliary or Spare Rims to Automobile Wheels. Albert Manson, Paris, France. Filed July 1, 1909. Serial No. 505,443.

1. In a device for attaching an additional rim to a vehicle wheel, a clamp composed of a double pair of hinged jaws each jaw having a curved portion for clamping to a part of a vehicle rim, and with side portions for clasping a wooden portion of the vehicle rim, the double pair of jaws being formed to clasp a wheel spoke between the same, in combination with bolts and corresponding spring controlled thumb turned nuts holding the jaws in place, and also holding the spoke securely within the jaws.

1,012,933. Means for Operating the Gasolene Tank Valves of Motor Cars. Charles Lee Thomas, Canisteo, N. Y. Filed Sept. 6, 1910. Serial No. 580,614.

1. Means for operating the gasolene tank valve of a motor car, having in combination a hollow casing provided with a key hole, a rotatable operating rod having at one end a clutch head capable of detachable engagement with the handle of said valve and at its opposite end portion a bolt seat and a wrench seat, and a movable bolt working in said casing and having releasable engagement with said bolt seat, said bolt having a cam-beveled outer face, and a key having a beveled end capable of engagement with the cam outer face of said bolt to release the same, and a recess capable of engagement with the wrench seat of said rod to turn the same.

1,012,936. Front Wheel Drive for Automobiles. Peter Turon, Los Angeles, Cal. Filed Dec. 27, 1909. Serial No. 535,188.

1. In combination with a chassis, the differential, and a divided front axle of an automobile, a casing for the axle, a pair of arms on each end of said casing, a journal pivoted thereto to turn in a horizontal plane, a wheel hub on the journal, said hub having notches in the end thereof, a driving shaft, a universal coupling in said driving shaft within the pivotal axis of said journal, said shaft extending slidably through said journal and provided at its outer end with a squared portion of the shaft, lugs on said plate engaging the notches in the hub, and means for yieldingly holding said plate in engagement with said journal and said hub comprising a cap adapted to fit over the end of said hub, and a coiled spring in said cap adapted to press against said plate.

1,012,951. Shoe for Tires. Cyrus A. Whyland, Marion, Mass. Filed Apr. 27, 1911. Serial No. 623,629.

An armor member consisting of a bent body portion adapted to be disposed around the tread of a tire, two flanges each having an orifice, extending laterally from the body portion, each end of the body portion being cut in two places to form central flanges bent over the body portion at its center, and wings which are bent laterally.

1,013,048. Spark Plug. Charles B. Nelson, Lindsborg, Kans. Filed Dec. 6, 1910. Serial No. 595,919.

A spark plug comprising a metal shell, a tubular body fitted to the lower end of the shell and having its intermediate portion contracted to form an annular electrode, a core of insulating material secured within the shell and having its lower end extending into the upper space of the tubular body, an electrode arranged within the core and having its lower end extending into the contracted space of the tubular body, and a ball valve located in the lower space of the tubular body and adapted to be moved upward by the force of explosion to close the lower end of the contracted portion of the tubular body.

1,013,082. Carburetter. Robert Symmonds, Jr., Kenosha, Wis., assignor to Thomas B. Jeffery, Kenosha, Wis. Filed Aug. 2, 1906. Serial No. 328,871.

In a carburetter for explosive engines, the combination with a primary mixing chamber having an inlet port for a combustible fluid and an outlet port for a combustible mixture, of means for supplying air to said mixing chamber, an auxiliary mixing chamber with which the primary mixing chamber communicates, a plurality of valves controlling air ports leading to said auxiliary mixing chamber, and springs of different tensions for retaining said valves seated, whereby said valves will successively open as the speed of the engine increases.

1,013,085. Tire for Vehicle Wheels. William T. Whitlock, Chicopee Falls, Mass., assignor to The Fisk Rubber Company, Chicopee Falls, Mass., a Corporation of Delaware. Filed Apr. 19, 1911. Serial No. 622,000.

In a resilient tire, a circumferential rib located on the median line of the tire, and a rib located on either side thereof equidistant therefrom, all of said ribs being substantially radial to the tread surface of the tire and integral therewith, and traction ribs extending from either side of said central rib, the outer ends of said traction ribs being spaced apart from the ribs on either side of said central rib.

1,013,273. Wheel. William W. Byam, Chicago, Ill. Filed May 24, 1910. Serial No. 563,132.

In a device of the class described, a rim composed of two circumferentially continuous annular sections having inwardly extending projections thereon, a transversely split channel lock ring having outwardly projecting side flanges, said rim sections resting upon the outer edges of said side flanges and being separated from the central part of said lock ring by a clearance space, said projections being received between said side flanges, and means for expanding said lock ring.

1,013,282. Vehicle Wheel. Hugh Duncan, Langside, Glasgow, Scotland. Filed June 26, 1911. Serial No. 635,281.

In a vehicle wheel, in combination, a rim, a tread consisting of a series of resilient sections supported on said rim, said sections each comprising a body portion, and flange members detachably securing said tread sections to said rim, said members having ribs, extending between the bases of said tread sections, and inturned lips engaging said bases and clamping the same immovably to said rim and extending part way between the body portions of said sections, said lips being recessed to receive said body portions.

1,013,293. Starting Device for Internal Combustion Engines. Anthony P. Hinsky, Brooklyn, N. Y. Filed May 2, 1911. Serial No. 614,618.

A cranking apparatus for internal combustion engines consisting of a supplemental shaft mounted in axial line with the crank shaft of the engine and movable toward and from the same and adapted to engage the same, a spring normally holding said supplemental shaft out of engagement with the crank shaft, a crank arm mounted on the outer end of the supplemental shaft and provided with an internal chamber, a gear mounted on said shaft within said chamber and keyed to said shaft, a handle spindle mounted in the outer end of said crank arm, a gear mounted on said spindle within said arm and keyed to said spindle, intermediate gears mounted in said arm and meshing with said first named gears and with each other, a ratchet wheel secured to the inner side of the said arm where the supplemental shaft passes therethrough and through which said supplemental shaft passes, and a plurality of suitably supported pawls adapted to engage said ratchet wheel.

1,013,374. Detachable Rim for Pneumatic Tires. Walter E. Copithorn, Natick, Mass. Filed June 20, 1910. Serial No. 567,779.

In a wheel, the combination with a wheel body, of a detachable tire-receiving rim, a circular expansible locking member for locking the detachable rim to the wheel body, and a single tapered screw screw-threaded into and extending transversely of the wheel body and co-acting with the locking member to expand it and thereby lock the rim in place.

1,013,384. Shock Absorber. Ernst Flentje, Cambridge, Mass. Filed Oct. 29, 1909. Serial No. 525,285.

In a shock absorber, the combination with a cylinder to contain liquid, of a piston therein, said piston having a plurality of ports, a valve for said ports situated above the piston, a U-shaped member secured to the valve and extending through the ports beneath the piston for limiting the upward movement of the valve, and a cushioning device on the U-shaped member.

1,013,387. Vehicle Rim. James E. Hale, Akron, Ohio, assignor to The Goodyear Tire and Rubber Company, Akron, Ohio, a Corporation of Ohio. Filed Sept. 11, 1911. Serial No. 648,725.

The combination with a vehicle wheel of a contractible ring mounted thereon, the outer face of said band provided with a shallow groove having inclined sides, a pair of wedge-shaped rings mounted in said groove, a rim mounted on said wedge-shaped rings, and means for forcing said wedge-shaped rings laterally away from each other to cause them to detachably engage the inner face of said rim for holding the latter in place and simultaneously compressing the said grooved ring on said vehicle wheel.

1,013,473. Vehicle Brake. Harald Eduard Frederick Rude Block, Copenhagen, Denmark. Filed Feb. 27, 1911. Serial No. 611,276.

In a motor car in combination, a wheel brake, means for operating same from the chauffeur's seat only, a releasable handle placed in the tonneau, a wire affixed to the said handle, with a round turn wound around the driving shaft of the motor and thereupon connected with the wheel brake, guide pulleys for the said wire and means for breaking the ignition of the motor, said latter means to be manipulated from the passengers' seats.

1,013,577. Vehicle Spring. Frank Wheeler, Orange, Cal. Filed July 5, 1910. Serial No. 570,493.

Digitized by Google

A vehicle spring structure comprising an axle engaging member, bell crank levers pivoted to the opposite ends of said axle member, and each formed with long and short arms, their shorter arms extending below the axle, a load supporting compression spring set between the ends of the depending shorter arms, the said bell crank levers also having abutment arms extending above the axle, a compression rebound spring set between said abutment arms, one bell-crank lever having integral spring seats upon its depending short arm and its abutment arm, while the other bell crank lever carries adjustable spring seats upon its arms adapted to be tightened against said springs sufficiently to prevent their displacement.

1,013,596. Tire. Alfred Freschl, Chicago, Ill. Filed July 8, 1908. Serial No. 442,522.

A tire comprising a body part and a detachable tread, the body part of the tire being yieldable and having upwardly extending overhanging side flanges, the tread member comprising a plurality of vertically extending relatively thin layers of yieldable material, the tread having a circumferentially extending cut out portion in each side whereby to form a projecting tongue to engage under the overhanging flange of the body part, and whereby to provide a circumferentially extending cutout portion in each side upper surface of said flange, and rods extending through the respective flanges of the body part, and through the various layers of the tread part, and means for adjusting said rods lengthwise whereby to bindingly engage the flanges of the body part with the tread part and to compress the layers of said tread part.

1,013,656. Spring Wheel. William D. Hester, Durham, N. C. Filed Dec. 16, 1910. Serial No. 597,602.

A spring wheel comprising a hub, a rigid metal rim, spokes connected to said hub and rim, a tire rim comprising curved sections pivotally connected together, studs projecting from some of said sections, said studs extending inwardly and adapted to move through holes in the rigid metal rim, said studs each having a bore or socket, a pin connected to the hub and mounted to move in said bore, and a spring surrounding said pin and bearing at one end against said stud, and lock nuts on said pin for adjusting the tension of said spring.
